

High Power LED Driver with Pre-Emptive Boost for Ultra-High Dimming Ratio and Low Output Ripple

FEATURES AND BENEFITS

- Automotive AEC-Q100 qualified
- Enhanced fault handling for ASIL B system compliance
- Wide input voltage range of 4.5 to 40 V for start/stop, cold crank, and load dump requirements
- Operate in Boost or SEPIC mode for flexible output
- Gate driver for external NMOS to deliver higher output power
- Four integrated LED current sinks, up to 210 mA each
- Boost switching frequency synced externally or programmed from 200 kHz to 2.3 MHz
- Programmable boost frequency dithering to reduce EMI
- Advanced control allows minimum PWM on-time down to 0.3 μ s, and avoids MLCC audible noises
- LED contrast ratio: 15,000:1 at 200 Hz using PWM dimming alone, 150,000:1 when combining PWM and analog dimming
- Excellent input voltage transient response even at lowest PWM duty cycle
- Gate driver for optional PMOS input disconnect switch
- Extensive fault protection features

DESCRIPTION

The A80601 is a multi-output LED driver for automotive applications such as exterior lighting, heads-up display, and mid-size LCD backlighting. It implements a current-mode boost/SEPIC converter with gate driver for external N-MOSFET. This allows greater output power even at minimum supply voltage.

The A80601 provides four integrated current sinks driving up to 210 mA per string. Multiple sinks can be paralleled together to achieve higher LED currents up to 840 mA. The IC operates from single power supply from 4.5 to 40 V; once started, it can continue to operate down to 4 V. This allows it to withstand stop/start, cold crank, and load dump conditions encountered in automotive systems.

The A80601 can control LED brightness through external PWM signal. By using the patented Pre-Emptive Boost control, an LED brightness contrast ratio of 15,000:1 can be achieved using PWM dimming at 200 Hz. A higher ratio of 150,000:1 is possible when using a combination of PWM and analog dimming.

PACKAGE:

24-Pin 4 mm \times 4 mm QFN with Wettable Flank

Not to scale

APPLICATIONS

- Automotive infotainment backlighting
- Automotive heads-up display
- Automotive interior and exterior lighting

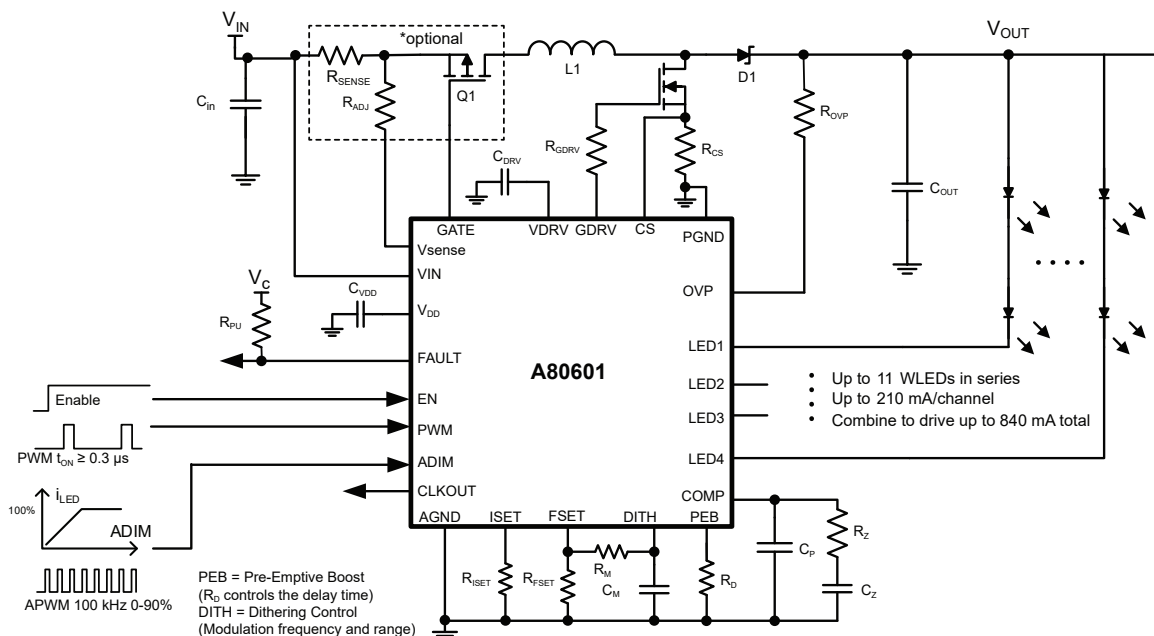

Figure 1: A80601 in Boost configuration where V_{OUT} is higher than V_{IN}

A80601 and A80601-1

High Power LED Driver with Pre-Emptive Boost for Ultra-High Dimming Ratio and Low Output Ripple

DESCRIPTION (continued)

Switching frequency can be externally synchronized or programmed between 200 kHz and 2.3 MHz. This allows operation either above or below the AM band. A programmable dithering feature further reduces EMI. A Clock-Out is provided for other converters to sync to the A80601.

The A80601 provides protection against output short, overvoltage, open- or shorted-LED pin, and overtemperature. A cycle-by-cycle current limit protects the external boost switch against high current overloads. An external P-MOSFET can optionally be used to disconnect input supply in case of output to ground short fault. The A80601-1 is similar to A80601 except it adopts ‘One-Out-All-Out’ fault handling (See Fault Table section for details).

SELECTION GUIDE [1]

Part Number	Fault Handling	LED Driver	Package	Packing
A80601KESJSR	One-Out-Continue	4 × 210 mA	24-pin 4 × 4 mm wettable flank QFN with exposed thermal pad and sidewall plating	6000 pieces per reel
A80601KESJSR-1	One-Out-All-Out

ABSOLUTE MAXIMUM RATINGS [2]

Characteristic	Symbol	Notes	Rating	Unit
LEDx Pin	V_{LEDx}	$x = 1..4$	-0.3 to 40	V
OVP pin	V_{OVP}		-0.3 to 40	V
VIN	V_{IN}		-0.3 to 40	V
VSENSE, GATE	V_{SENSE}, V_{GATE}		Higher of -0.3 and $(V_{IN} - 7.4)$ to $V_{IN} + 0.4$	V
VDRV, GDRV	V_{DRV}, V_{GDRV}		-1.0 to 7.5	V
CS	V_{CS}		-0.3 to 7	V
EN, PWM, FAULT, ADIM, CLKOUT, COMP, DITH, PEB, FSET, ISET, VDD		External input signals must not be higher than $V_{IN} + 0.4$ V	-0.3 to 5.5	V
Operating Ambient Temperature	T_A	Range K	-40 to 125	°C
Maximum Junction Temperature	$T_{J(max)}$		150	°C
Storage Temperature	T_{stg}		-55 to 150	°C

[2] Stresses beyond those listed in this table may cause permanent damage to the device. The absolute maximum ratings are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the Electrical Characteristics table is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

THERMAL CHARACTERISTICS: May require derating at maximum conditions; see application information

Characteristic	Symbol	Test Conditions [4]	Value	Unit
Package Thermal Resistance	$R_{\theta JA}$	ES package measured on 4-layer PCB based on JEDEC standard	37	°C/W

[4] Additional thermal information available on the Allegro website.

Figure 3: Functional Block Diagram

PINOUT DIAGRAM AND TERMINAL LIST

Package ES, 24-Pin QFN Pinouts

Terminal List Table

Number	Name	Function
1	FAULT	This pin is an open drain type configuration that will be pulled low when a fault occurs. Connect a pull-up resistor between this pin and desired logic level voltage.
2	VDD	Output of internal LDO (bias regulator). Connect a 1 μ F decoupling capacitor between this pin and AGND. V_{DD} is regulated at \sim 4.25 V.
3	AGND	LED current Ground. Also serves as 'quiet' ground for analog signals.
4	COMP	Output of the error amplifier and compensation node. Connect a series R_Z - C_Z network from this pin to AGND for control loop compensation.
5	ISET	Connect R_{ISET} resistor between this pin and AGND to set the 100% LED current.
6	PEB	Pre-Emptive Boost control: Connect resistor from PEB pin to AGND to fine-tune the delay between boost switch and LED current sinks. Leave pin open for minimum PEB delay of 1 μ s.
7	DITH	Dithering control: connect a capacitor to AGND to set the dithering modulation frequency (1 to 22 kHz). Connect a resistor between DITH and FSET pins to set the dithering range (such as \pm 5% of f_{SW}).
8	FSET	Frequency/Synchronization pin. A resistor R_{FSET} from this pin to AGND sets the switching frequency f_{SW} (with dithering superimposed) between 200 kHz and 2.3 MHz. It can also be used to synchronize f_{SW} to an external frequency between 260 kHz and 2.3 MHz (frequency dithering is disabled in this case).
9	ADIM	Analog dimming. Apply a PWM clock (40 to 1000 kHz) to pin and the duty cycle of this clock determines the LED current. Alternatively, apply DC level between 0.2 and 2 V to vary LED current between 10% and 100%. If unused, pull pin above 2 V for 100%.
10	PWM	Controls the on/off state of LED current sinks to reduce the light intensity by using pulse-width modulation. Typical PWM dimming frequency is in the range of 200 Hz to 2 kHz. EN and PWM pins may be tied together to allow single-wire dimming control.
11	EN	Enables the IC when this pin is pulled high. If EN goes low, the IC remains in standby mode for up to 16 ms, then shuts down completely.
12	CLKOUT	Logic output representing the switching frequency of internal boost oscillator. This allows other converters to be synchronized to the same f_{SW} with the same dithering modulation, if applicable. Output is active as long as IC is enabled.
13-16	LED4..LED1	LED current sinks #4 to #1. Connect the cathode of each LED string to pin. Unused LED pin must be terminated to AGND through a 2.37 k Ω resistor.
17	OVP	Overvoltage Protection. Connect external resistor from VOUT to this pin to adjust the overvoltage protection threshold.
18	PGND	Power Ground for internal Gate Driver. Connect pin to external power GND with shortest path.
19	VDRV	Gate driver supply voltage (\sim 6.5 V). Connect a 2.2 μ F MLCC to PGND for buffer.
20	CS	Current Sense for peak current control of power switch. Connect to sense resistor at the Source terminal of external power MOSFET.
21	GDRV	Gate driver for power switch. Connect to Gate of external power MOSFET. (External FET must be fully enhanced at $V_{GS} = 5$ V).
22	GATE	Output gate driver pin for external P-channel MOSFET (input disconnect switch).
23	VSENSE	Connect this pin to the negative sense side of the input current sense resistor R_{SC} . The threshold voltage is measured as $V_{IN} - V_{SENSE}$. There is also fixed i_{ADJ} current sink to allow for trip threshold adjustment.
24	VIN	Input power to the IC as well as the positive side of input current sense resistor.
-	PAD	Exposed pad of the package providing enhanced thermal dissipation. Must be connected to the ground plane(s) of the PCB with at least 8 vias, directly in the pad.

[1] For input and output current specifications, negative current is defined as coming out of the node or pin (sourcing); positive current is defined as going into the node or pin (sinking).

[2] Ensured by design and characterization; not production tested.

[3] Minimum $V_{IN} = 4.5\ \text{V}$ is only required at startup. After startup is completed, IC can continue to operate down to $V_{IN} = 4\ \text{V}$.

[4] LED current is trimmed to cancel variations in both Gain and ISET voltage.

APPLICATION EXAMPLES

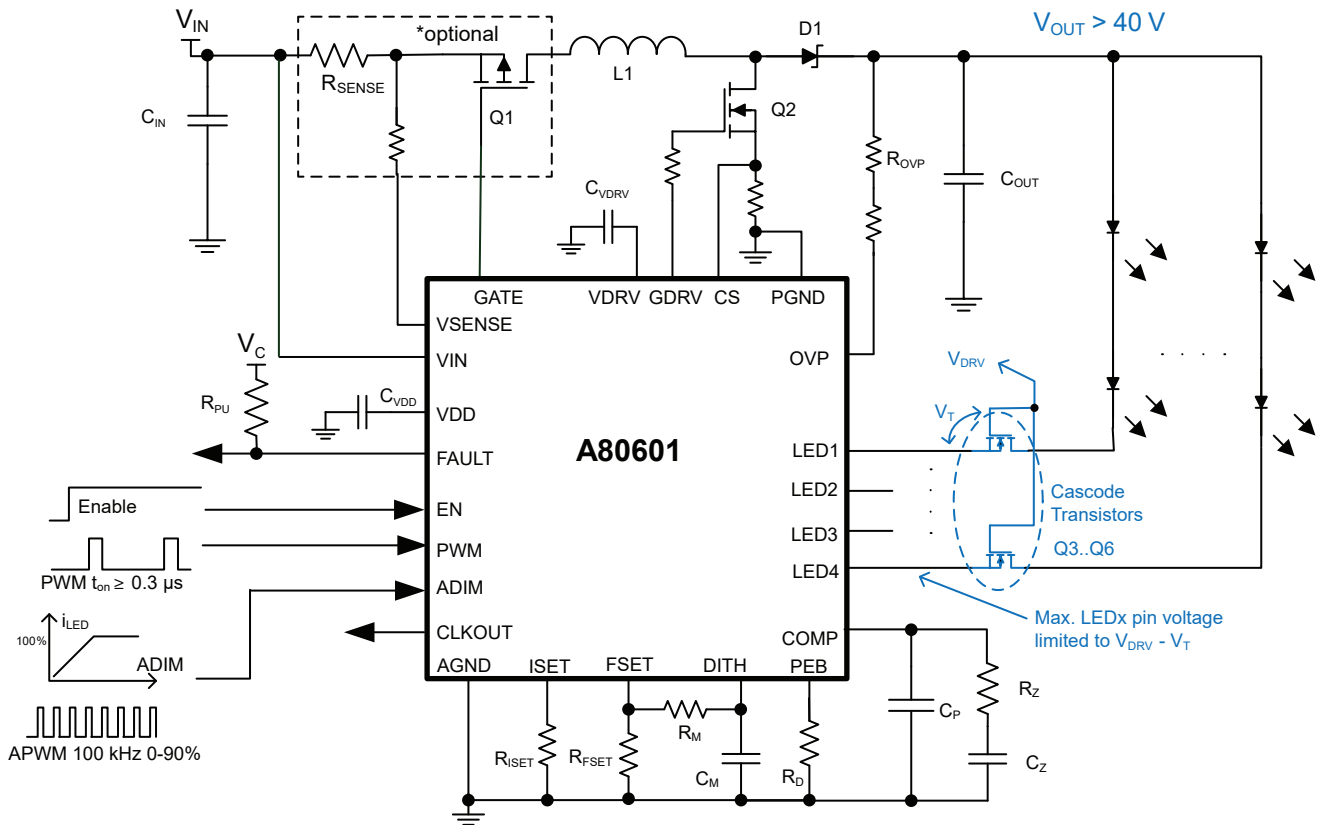

Figure 4: Cascode transistors can be used in case V_{OUT} needs to be higher than 40 V

To drive an output load with more than 11 white LEDs in series, the above application circuit can be used. The cascode transistors Q3..Q6 limits LED1-4 pin voltages to $V_{DRV} - V_T$, even in case of LED string direct short. (V_T = threshold voltage of transistor, typically under 3 V).

The cascode transistors can be any small-signal N-channel MOSFET, rated for the maximum output voltage and LED current per channel. As an example: consider T2N7002BK in SOT23 package. It is rated for 60 V breakdown and 400 mA continuous current.

FUNCTIONAL DESCRIPTION

The A80601 is a multi-string LED regulator with four precision current sinks and a gate driver for external boost MOSFET switch. It incorporates a patented Pre-Emptive Boost (PEB) control algorithm to achieve PWM dimming ratio over 15,000:1 at 200 Hz. PEB control also minimizes output ripple to avoid audible noise from output ceramic capacitors.

The switching frequency can be either synchronized to an external clock or generated internally. Spread-spectrum technique (with user-programmable dithering range and modulation frequency) is provided to reduce EMI. A clock-out signal (CLK-OUT) allows other converters to be synchronized to the switching frequency of A80601.

Enabling the IC

The A80601 wakes up when EN pin is pulled above logic high level, provided that VIN pin voltage is over the VIN_UVLO threshold. The boost stage and LED channels are enabled separately by PWM = H signal after the IC powers up.

The IC performs a series of safety checks at power up, to determine if there are possible fault conditions that might prevent the system from functioning correctly. Power-up checks include:

- VOUT shorted to GND
- LED pin shorted to GND
- FSET pin open/shorted
- ISET pin open/shorted to GND, etc.

Only if no faults were detected, then the IC can proceed to start switching.

As long as EN = H, the PWM pin can be toggled to control the brightness of LED channels by using PWM dimming. Alternatively, EN and PWM can be tied together to allow single-wire control for both power on/off and PWM dimming. If EN is pulled low for longer than 16 ms, the IC shuts off.

Figure 6: Startup showing EN, VDD, CLKOUT, and ISET (PWM = L).
Note that CLKOUT is available as soon as VDD ramps up, even though Boost stage and LED drivers are not yet enabled.

Powering Up: LED Detection Phase

The VIN pin has an undervoltage lockout (UVLO) function that prevents the A80601 from powering up until the UVLO threshold is reached. Once the VIN pin goes above UVLO and a high signal is present on the EN pin, the IC proceeds to power up. At this point, the A80601 is going to enable the disconnect switch and will try to check if any LED pins are shorted to GND and/or are not used. The LED detection phase starts when PWM = H and the GATE voltage of the input disconnect PMOS switch is pulled down to 3.3 V below V_{IN} .

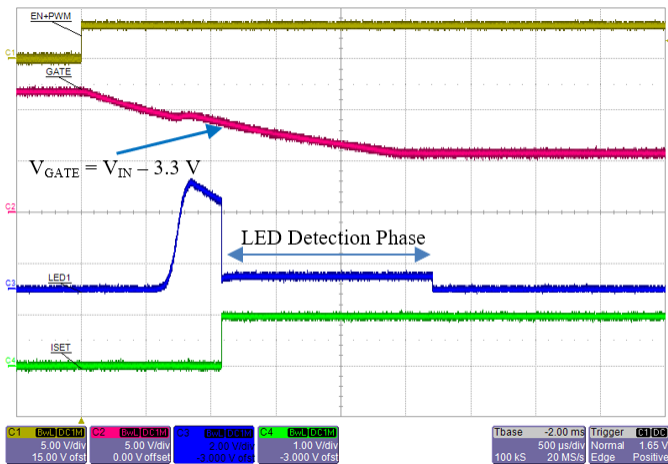

Figure 7: Startup showing EN+PWM, GATE, LED1, and ISET. Note that LED Detection Phase starts as soon as GATE pin is pulled down to 3.3 V below V_{IN} (provided that PWM = H).

Once the voltage threshold on VLED pins exceeds ~120 mV, a delay of approximately 1.5 ms is used to determine the status of the pins.

Unused LED pin should be terminated with a 2.37 k Ω resistor to GND. At the end of LED detection phase, any channel with pull down resistor is then disabled and will not contribute to the boost regulation loop.

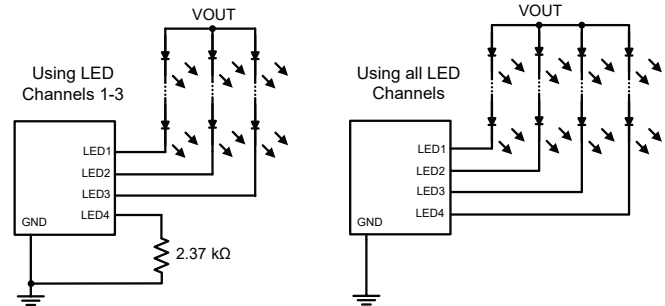

Figure 8: How to signal an unused LED channel during startup LED detection phase

Table 1: LED Detection phase voltage threshold levels

LED Pin Voltage Measured	Interpretation	Outcome
< 120 mV	LED pin shorted to GND fault	Cannot proceed with soft-start unless fault is removed
~ 230 mV	LED channel not in use	LED channel is removed from operation
> 340 mV	LED channel in use	Proceed with soft-start

Figure 9: Normal startup showing all channels passed LED Detection phase (only LED1 and LED2 pin voltages are shown). Total LED current = 100 mA × 4.

Figure 10: Normal startup showing LED1 channel is disabled with a 2.37 kΩ resistor to GND. Total LED current = 100 mA × 3.

If an LED pin is shorted to ground, the A80601 will not proceed with soft start until the short is removed from the LED pin. This prevents the A80601 from ramping up the output voltage and putting an uncontrolled amount of current through the LEDs.

The FAULT pin is pulled low in case of LED pin shorted-to-GND fault, but the IC continues to retry. Once the fault is removed, the soft-start process will continue. The same applies in case of FSET or ISET pin is shorted to GND.

Figure 11: LED1 is shorted-to-GND initially, then released. After the fault is removed, the IC auto-recovers and proceeds with soft-start. FAULT is released at the end of LED detection phase.

Power Up: Boost Output Undervoltage

During startup, after the input disconnect switch has been enabled, the output voltage is checked through the OVP (over-voltage protection) pin. If the sensed voltage does not rise above $V_{UVP(th)}$, the output is assumed to be at fault and the IC will not proceed with soft start. Output UVP level is linked to the OVP level programmed according to the equation:

$$V_{UVP} = V_{OVP} / 12$$

Undervoltage protection may be caused by one of the following faults:

- Output capacitor shorted to GND
- Boost inductor or diode open
- OVP sense resistor open

After an UVP (undervoltage protection) fault, the A80601 is immediately shutdown and latched off. To enable the IC again, the latched fault must be cleared. This can be achieved by powering-cycling the IC, which means either:

- V_{IN} falls below falling UVLO threshold, or
- $EN = L$ for >16 ms.

Alternatively, latched fault can be cleared by keeping $EN = H$ but pulling $PWM = L$ for >16 ms. This method has the advantage that it does not interrupt the CLKOUT signal.

Soft Start Function

During startup, the A80601 ramps up its boost output voltage following a fixed slope, as determined by OVP set point and Soft-Start Timer. This technique limits the input inrush current, and ensures consistent startup time regardless of the PWM dimming duty cycle.

The soft-start process is completed when any one of the following conditions is met:

- All enabled LED channels have reached their regulation current,
- Output voltage has reached 93% of its OVP threshold, or
- Soft-start ramp time (t_{SS}) has expired.

To summarize, the complete startup process of A80601 consists of:

- Power-up error checking
- Enabling input disconnect switch
- LED pin open/short detection
- Soft-start ramp

This is illustrated by the following startup timing diagram (not to scale):

Figure 12: Complete startup process of A80601

Explanation of Events:

- A:** $EN = H$ wakes up the IC. V_{DD} ramps up and CLKOUT becomes available. IC starts to pull down GATE slowly.
- B:** When GATE is pulled down to 3.3 V below V_{IN} , I_{SET} becomes enabled. IC is now waiting for $PWM = H$ to startup.
- C:** Once $PWM = H$, the IC checks each LEDx pins to determine if it is in use, disabled, or shorted to GND.
- D:** Soft-Start begins at the completion of LED pin short-detect phase of ~1.5 ms. V_{OUT} ramps up following a fixed slope set by OVP and soft-start timer of ~8 ms.
- E:** Soft-start terminates when all LED currents reached regulation, V_{OUT} reached 93% OVP, or soft-start timer expired.

Frequency Selection

The switching frequency of the boost regulator is programmed by a resistor connected to FSET pin. The switching frequency can be selected anywhere from 200 kHz to 2.3 MHz. The chart below shows the typical switching frequency versus FSET resistor value.

Figure 13: Switching Frequency as a function of FSET Resistance

Alternatively, the following empirical formula can be used:

$$\text{Equation 1: } f_{SW} = 21.5 / (R_{FSET} + 0.2)$$

where f_{SW} is in MHz and R_{FSET} is in kΩ.

If a fault occurs during operation that will increase the switching frequency, the internal oscillator frequency is clamped to a maximum of 3.5 MHz. If the FSET pin is shorted to GND, the part will shut down. For more details, refer to the Fault Mode Table section.

Synchronization

The A80601 can also be synchronized using an external clock. At power up, if the FSET pin is held low, the IC will not start. Only when the FSET pin is tristated to allow for the pin to rise to about 1 V, or when a sync clock is detected, the A80601 will then try to power up.

The basic requirement of the external sync signal is 150 ns minimum on-time and 150 ns minimum off time. The diagram below shows the timing restrictions for a synchronization clock at 2.2 MHz.

Figure 14: Pulse width requirements for an External Sync clock at 2.2 MHz

Based on the above, any clock with a duty cycle between 33% and 66% at 2.2 MHz can be used. The table below summarizes the allowable duty cycle range at various synchronization frequencies.

Table 2: Acceptable Duty Cycle range for External Sync clock at various frequencies

Sync. Pulse Frequency	Duty Cycle Range
2.2 MHz	33% to 66%
2 MHz	30% to 70%
1 MHz	15% to 85%
600 kHz	9% to 91%
300 kHz	4.5% to 95.5%

If it is necessary to switch over between internal oscillator and external sync during operation, ensure the transition takes place at least 500 ns after the previous PWM = H rising edge. Alternatively, execute the switchover during PWM = L only. This restriction does not apply if PWM dimming is not being used.

Figure 15: Avoid switching over between Internal Oscillator and External Sync in highlighted region

Loss of External Sync Signal

Suppose the A80601 started up with a valid external SYNC signal, but the SYNC signal is lost during normal operation. In that case, one of the following happens:

- If the external SYNC signal is high impedance (open), the IC continues normal operation after approximately 5 μ s, at the switching frequency set by R_{FSET} . No FAULT flag is generated.
- If the external SYNC signal is stuck low (shorted to ground), the IC will detect an FSET-shorted-to-GND fault. FAULT pin is pulled low after approximately 10 μ s, and switching is disabled. Once the FSET pin is released or SYNC signal is detected again, the IC will proceed to soft-start.

To prevent generating a fault when the external SYNC signal is stuck at low, the circuit shown below can be used. When the external SYNC signal goes low, the IC will continue to operate normally at the switching frequency set by the R_{FSET} . No FAULT flag is generated.

**Figure 16: Countermeasure for
External Sync Stuck-at-Low Fault**

It is important to use a small capacitance for the AC-coupling capacitor (220 pF in the above example). If the capacitance is too large, the IC may incorrectly declare a FSET-shorted-to-GND fault and restart.

Switching Frequency Dithering

To minimize the peak EMI spikes at switching frequency harmonics, the A80601 offers the option of frequency dithering, or spread-spectrum clocking. This feature simplifies the input filters needed to meet the automotive CISPR 25 conducted and radiated emission limits.

For maximum flexibility, the A80601 allows both dithering range and modulation frequency to be independently programmable using two external components.

The Dithering Modulation Frequency is given by the approximate equation:

$$\text{Equation 2: } f_{DM} (\text{kHz}) = 25 / C_{DITH} (\text{nF})$$

where C_{DITH} is the value of capacitor connected from DITH pin to GND.

The dithering Range is given by the approximate equation:

$$\text{Equation 3: } \text{Range } (\pm\%) = 20 \times R_{FSET} / R_{DITH}$$

where R_{FSET} is the resistor from FSET pin to GND, R_{DITH} is the resistor between DITH and FSET pins.

As an example, by using $R_{FSET} = 10 \text{ k}\Omega$, $R_{DITH} = 40.1 \text{ k}\Omega$, and $C_{DITH} = 22 \text{ nF}$, the resulted switching frequency is $f_{SW} = 2.15 \text{ MHz} \pm 5\%$ modulated at 1.1 kHz . This is illustrated by the following diagram.

Figure 17: How to Program Switching Frequency Dithering Range and Modulation Frequency

There are no hard limits on dithering range and modulation frequency. As a general guideline, pick a dithering range between $\pm 5\%$ and 10% , with the modulation frequency between 1 kHz and 3 kHz . In practice, using a larger dithering range and/or higher modulation frequency do not generate any noticeable benefits.

If dithering function is not desired, it can be disabled by disconnecting the R_{DITH} between DITH and FSET pins. Connect DITH pin to VDD if C_{DITH} is not populated. Dithering is always disabled when f_{SW} is controlled by external sync. R_{DITH} and C_{DITH} have no effects in this case even if they were populated.

Clock Out Function

The A80601 allows other ICs to be synchronized to its internal switching frequency through the CLKOUT pin.

The CLKOUT signal is available as soon as the IC is enabled ($EN = H$), even when the boost stage is not active ($PWM = L$). Its frequency is the same as that of the internal oscillator. Its duty cycle, however, depends on how the switching frequency is generated:

- If f_{SW} is programmed by FSET resistor, the CLKOUT duty cycle is approximately 50% .
- If f_{SW} is controlled by external sync, the output signal has a fixed 150 ns negative pulse width ($CLKOUT = L$), regardless of the external sync frequency.

This is illustrated by the following waveforms:

Figure 18: Without external sync, the CLKOUT signal has a fixed duty cycle of 50% . Delay from CLKOUT falling edge to SW falling edge is approximately 50 ns .

Figure 19: With external sync, the CLKOUT signal has a fixed negative pulse width of 200 ns. Delay from SYNC rising edge to CLKOUT falling edge is approximately 60 ns.

LED Current Setting

The maximum LED current can be up to 210 mA per channel, and is set through the ISET pin. Connect a resistor R_{ISET} between this pin and GND. The relation between I_{LED} and R_{ISET} is given below:

Equation 4:

$$I_{LED} = I_{SET} \times A_{ISET}$$

$$I_{SET} = V_{ISET} / R_{ISET}$$

Therefore $R_{ISET} = (V_{ISET} \times A_{ISET}) / I_{LED}$

$$= 1444 / I_{LED}$$

where I_{LED} current is in mA and R_{ISET} is in $k\Omega$.

This sets the maximum current through the LEDs, referred to as the '100% current'. The average LED current can be reduced from the 100% current level by using either PWM dimming or analog dimming.

Table 3: ISET resistor values vs. LED current. Resistances are rounded to the nearest E-96 (1%) resistor value.

Standard Closest R _{ISET} Resistor Value	LED current per channel
7.15 k Ω	200 mA
9.53 k Ω	150 mA
14.3 k Ω	100 mA
19.1 k Ω	75 mA
28.7 k Ω	50 mA

PWM Dimming

When both EN and PWM pins are pulled high, the A80601 turns on all enabled LED current sinks. When either EN or PWM is pulled low, all LED current sinks are turned off. The compensation (COMP) pin is floated, and critical internal circuits are kept active.

Figure 20: PWM dimming operation at 20% 1 kHz. CH1 = PWM (5 V/div), CH2 = SW (20 V/div), CH3 = V_{OUT} , CH4 = i_{LED} (200 mA/div).

By using the patented Pre-Emptive Boost (PEB) control algorithm, the A80601 is able to achieve minimum PWM dimming on-time down to 300 ns. This translates to PWM dimming ratio up to 15,000:1 at the PWM dimming frequency of 200 Hz. Technical details on PEB will be explained in the next section.

Figure 21: Zoom in view for PWM on-time = 10 μ s. Notice that the LED current is shifted with respect to PWM signal. Ripple at V_{OUT} is \sim 0.2 V when using $2 \times 4.7 \mu$ F MLCC as output capacitors.

A80601 and A80601-1

High Power LED Driver with Pre-Emptive Boost for Ultra-High Dimming Ratio and Low Output Ripple

Figure 22: Zoom-in view showing A80601 is able to regulate LED current at PWM on-time down to 300 ns.

The typical PWM dimming frequencies fall between 200 Hz and 1 kHz. There is no hard limit on the highest PWM dimming frequency that can be used. However at higher PWM frequency, the maximum PWM dimming ratio will be reduced. This is shown in the following table:

Table 4: Maximum PWM Dimming Ratio that can be achieved when operating at different PWM Dimming Frequency

PWM Frequency	PWM Period	Maximum PWM Dimming Ratio
200 Hz	5 ms	15,000:1
1 kHz	1 ms	3,000:1
3.3 kHz	300 μs	1,000:1
20 kHz	50 μs	150:1

Pre-Emptive Boost

The basic principle of pre-emptive boost (PEB) can be best explained by the following two waveforms. The first one shows how a conventional LED driver operates during PWM dimming operation. The second one shows that of the A80601.

Common test conditions for both cases:

PWM = 1% at 1 kHz (on-time = 10 μs), $f_{SW} = 2.15$ MHz,
 $L = 10$ μH, $V_{IN} = 12$ V, LED load = 8 series ($V_{OUT} \approx 25$ V)
 at 100 mA × 4. $C_{OUT} = 2 \times 4.7$ μF 50 V 1210 MLCC.
 COMP: $R_Z = 280$ Ω, $C_Z = 68$ nF.

Common scope settings:

CH1 (Yellow) = PWM (5 V/div); CH2 (Red) = Inductor current (500 mA/div); CH3 (Blue) = V_{OUT} (1 V/div); CH4 (Green) = LED current (200 mA/div); time scale = 2 μs/div.

Figure 23: Traditional PWM Dimming operation where boost switch and LED current are enabled at the same time. Note that V_{OUT} shows overall ripple of ~0.5 V

When PWM signal goes high, a conventional LED driver turns on its boost switching at the time with LED current sinks. The problem is that the inductor current takes several switching cycles to ramp up to its steady-state value before it can deliver full power to the output load. During the first few cycles, energy to the LED load is mainly supplied by the output capacitor, which results in noticeable dip in output voltage.

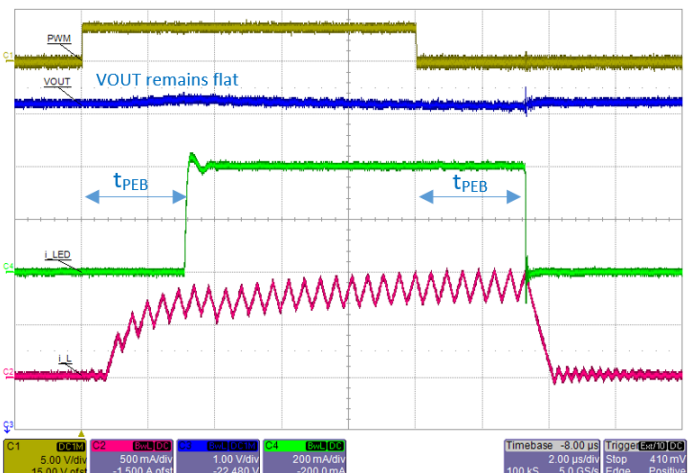

Figure 24: A80601 PWM dimming operation with PEB delay set to 3 μs. Note that V_{OUT} ripple is reduced to ~0.2 V.

In the A80601, the boost switch is also enabled when PWM goes high. However, the LED current is not turned on until after a short delay of t_{PEB} . This allows the inductor current to build up before it starts to deliver the full power to LED load. During the pre-boost period, V_{OUT} actually bumps up very slightly, while the following dip is essentially eliminated. When PWM goes low, both boost switching and LED remains active for the same delay of t_{PEB} . Therefore the PWM on-time is preserved in LED current.

PEB delay can be programmed using an external resistor, R_{PEB} , from PEB pin to GND. Their relationship is shown in the following chart:

Figure 25: How PEB delay time varies with value of PEB pin resistor to GND.

Ideally, t_{PEB} is equal to the inductor current ramp up time. But the latter is affected by many external parameters, such as switching frequency, inductance, V_{IN} and V_{OUT} ratio, etc. Therefore, some experimentation is required to optimize the PEB delay time. In general for switching frequency at 2 MHz, $t_{PEB} = 2.5$ to $4 \mu s$ is a good starting point.

The advantage of PEB is that even a non-optimized delay time can significantly reduce the output ripple voltage compared to a conventional LED driver.

Analog Dimming

The peak (100%) level of LED current is set by the R_{ISET} resistor. The actual peak LED current may also be adjusted continuously from approximately 10% up to 100%, by using the ADIM pin. There are two methods to do so:

1. In ADIM mode: apply a DC voltage between 0.2 V and 2 V at the pin.
2. In APWM mode: apply a clock signal with duty cycle between 90% and 0% at the pin.

ADIM MODE

An analog voltage is applied at the ADIM/APMW pin. This DC voltage linearly controls the peak LED current, as illustrated by the chart below:

Figure 26: In analog dimming mode, the LED current is linearly proportional to ADIM voltage between 0.2 V and 2 V approximately

There is an internal pull-down resistor (50 kΩ typical) from ADIM pin to GND. When this pin is left floating, LED current is actually being dimmed down to ~10%. Therefore, if analog dimming is not required, the ADIM pin should be pulled to over 2 V (but below V_{DD}) to ensure 100% LED current. One simple technique is to pull up ADIM to VDD through a 30 kΩ resistor.

APWM MODE

When a clock signal is detected at ADIM pin, the A80601 goes into APWM mode. The typical APWM signal frequency is between 40 kHz and 1 MHz. The duty cycle of this signal is inversely proportional to the percentage of current delivered to the LED. The relationship is shown below:

Figure 27: Showing LED current is inversely proportional to the APWM duty cycle. Test conditions: $V_{IN} = 12\text{ V}$, $V_{OUT} = 25\text{ V}$ ($8 \times$ WLED), total LED current = $100\text{ mA} \times 4$, APWM frequency = 100 kHz

As an example, a system that delivers a full LED current of 100 mA per channel would deliver 75 mA when an APWM signal with a duty-cycle of 25% is applied (because analog dimming level is $100\% - 25\% = 75\%$). This is demonstrated by the following waveforms.

Figure 28: PWM = H. Total LED current drops from 400 mA ($4 \times 100\text{ mA/ch}$) to 300 mA when APWM of 25% duty cycle is applied. Note that LED current takes $\sim 0.5\text{ ms}$ to settle after change in APWM.

Figure 29: PWM = 25% at 1 kHz . Peak LED current drops from 400 mA ($4 \times 100\text{ mA/ch}$) to 300 mA when APWM of 25% duty cycle is applied

One popular application of analog dimming is for LED brightness calibration, commonly known as ‘LED Binning’. LEDs from the same manufacturer and series are often grouped into different ‘bins’ according to their light efficacy (lumens per watt). It is therefore necessary to calibrate the ‘100% current’ for each LED bin, in order to achieve uniform luminosity.

To use ADIM pin as a trim function, the user should first set the 100% current based on efficacy of LED from the lowest bin. When using LED with higher efficacy, the required current is then trimmed down to the appropriate level using APWM duty cycle.

As an example, assume that:

- LED from lowest bin has an efficacy of 80 lm/W
- LED highest bin has an efficacy of 120 lm/W

Suppose the maximum LED current was set at 100 mA based on LEDs from lowest bin. When using LEDs from highest bin, the current should then be reduced to 67% (80/120). This can be achieved by sending APWM clock with 33% duty cycle.

Extending LED Dimming Ratio

The dynamic range of LED brightness can be further extended, by using a combination of PWM duty cycle, APWM duty cycle, and analog dimming method.

For example, the following approach can be used to achieve a 100,000:1 dimming ratio at 200 Hz:

- Vary PWM duty cycle from 100% down to 0.01% to give 10,000:1 dimming. This requires PWM dimming on-time be reduced down to 0.5 μ s.
- With PWM dimming on-time fixed at 0.5 μ s, vary APWM duty from 0% to 90% to reduce peak LED current from 100% down to 10%. This gives a net effect of 100,000:1 dimming.

Figure 30: How to achieve 100,000:1 dimming ratio by using both PWM and APWM. Test conditions: $V_{IN} = 12$ V, $V_{OUT} = 25$ V ($8 \times$ WLED), total LED current = 400 mA, PWM frequency = 200 Hz, APWM frequency = 100 kHz.

Note that the A80601 is capable of providing analog dimming range greater than 10:1. By applying APWM with 96% duty cycle, for example, an analog dimming range of 25:1 can be achieved. However, this requires the external APWM signal source to have very fine pulse-width resolution. At 200 kHz APWM frequency, a resolution of 50 ns is required to adjust its duty cycle by 1%.

Analog Dimming with External Voltage

Besides using ADIM pin, the LED current can also be reduced by using an external voltage source applied through a resistor to the ISET pin. The dynamic range of this type of dimming is dependent on the ISET pin current. The recommended i_{ISET} range is from 20 μA to 144 μA for the A80601. Note that the IC will continue to work at i_{ISET} below 20 μA , but the relative error in LED current becomes larger at lower dimming level.

Below is a typical application circuit using a DAC (digital-analog converter) to control the LED current. The ISET current (which directly controls the LED current) is normally set as V_{ISET}/R_{ISET} . The DAC voltage can be higher or lower than V_{ISET} , thus adjusting the LED current to a lower or higher value.

Figure 31: Adjusting LED current with an external voltage source

Equation 5:

$$i_{ISET} = \frac{V_{ISET}}{R_{ISET}} \left[\frac{VDAC - V_{ISET}}{R2} \right]$$

where V_{ISET} is the ISET pin voltage (typically 1.0 V), and VDAC is the DAC output voltage.

When VDAC is higher than 1.00 V, the LED current is reduced. When VDAC is lower than 1.00 V, the LED current is increased.

Some common applications for the above scheme include:

- LED binning
- Thermal fold-back using external NTC (negative temperature coefficient) thermistor

In the following application example, the thermistor used is NTC-S0805E3684JXT (680 k Ω @ 25°C). R1 = 336 k Ω , R2 = 20 k Ω , and R3 = 8.45 k Ω . The LED current per channel is reduced from 97 mA at 25°C to 34 mA at 125°C.

Figure 32: Thermal foldback of LED current using NTC thermistor
ILED VS Temperature with NTC Circuit

Figure 33: LED current varies with temperature when using thermistor NTC-S0805E3684JXT for thermal foldback

A80601 and A80601-1

High Power LED Driver with Pre-Emptive Boost for Ultra-High Dimming Ratio and Low Output Ripple

VDD

The VDD pin provides regulated bias supply for internal circuits. Connect a C_{VDD} capacitor with a value of 1 μF or greater to this pin. The internal LDO can deliver up to 2 mA of current externally with a typical VDD voltage of about 4.25 V. This allows it to serve as the pull up voltage for FAULT pin.

VDRV

The VDRV pin provides a regulated gate driver supply for external boost power MOSFET. Connect a C_{VDRV} capacitor with a typical value of 2.2 μF to this pin. The gate driver can deliver up to 2 A of peak sink and source current, with a typical V_{DRV} voltage of 6.5 V. However, its average output current is limited to approximately 36 mA. Note that average gate driver current is:

$$\text{Equation 6: } i_{VDRV} = f_{SW} \times Q_G$$

where f_{SW} is the switching frequency and Q_G is the total gate charge of the power MOSFET for $V_{GS} = 0$ to 6.5 V.

At higher switching frequency, it is important to select a power MOSFET with low Q_G to limit the average gate driver current. Refer to the appendix section for details on MOSFET selection.

Shutdown

If EN pin is pulled low for longer than $t_{EN(OFF)}$ (~16 ms), the A80601 enters shutdown (sleep mode). The next time EN pin goes high, all internal fault registers are cleared. The IC needs to go through a complete soft start process after PWM goes high.

Figure 34: After EN = L for ~16 ms, the IC completely shuts down so VDD (Blue) decays.

There is an alternative way to reset the internal fault status registers. By keeping EN = H and PWM = L for longer than 16 ms, the A80601 clears all internal fault registers but does not go into sleep mode. The next time PWM pin goes high, the IC will still go through soft start process. The difference is that VDD voltage and CLKOUT signal are always available as long as EN = H.

Figure 35: As long as EN = H, the IC does not shut down VDD and CLKOUT. But internal latched faults are cleared by PWM = L for ~16 ms.

FAULT DETECTION AND PROTECTION

FAULT Status

The FAULT pin is an open-drain output that will be pulled low when a fault occurs. A pull-up resistor (typically around 10 kΩ) is required between this pin and desired logic level voltage (typically 3.3 to 5 V). Multiple devices with open-drain FAULT pins can be connected in parallel to form a wired-AND configuration. This way, when any device reports a fault, the system FAULT signal is pulled low.

The A80601-1 (One-Out-All-Out option) has a bidirectional FAULT pin. This means the same pin also serves as an input to monitor the status of system FAULT signal. When the FAULT pin is pulled low externally for $>8 f_{SW}$ cycles by another device, the A80601-1 disables its own boost switch and all LED current sinks in response. This feature is required in Master/Slave configuration, for example.

The following two simplified flow charts demonstrate the difference between A80601 (unidirectional FAULT pin) and A80601-1 (bidirectional FAULT pin).

Figure 36: Simplified A80601 Startup Flowchart

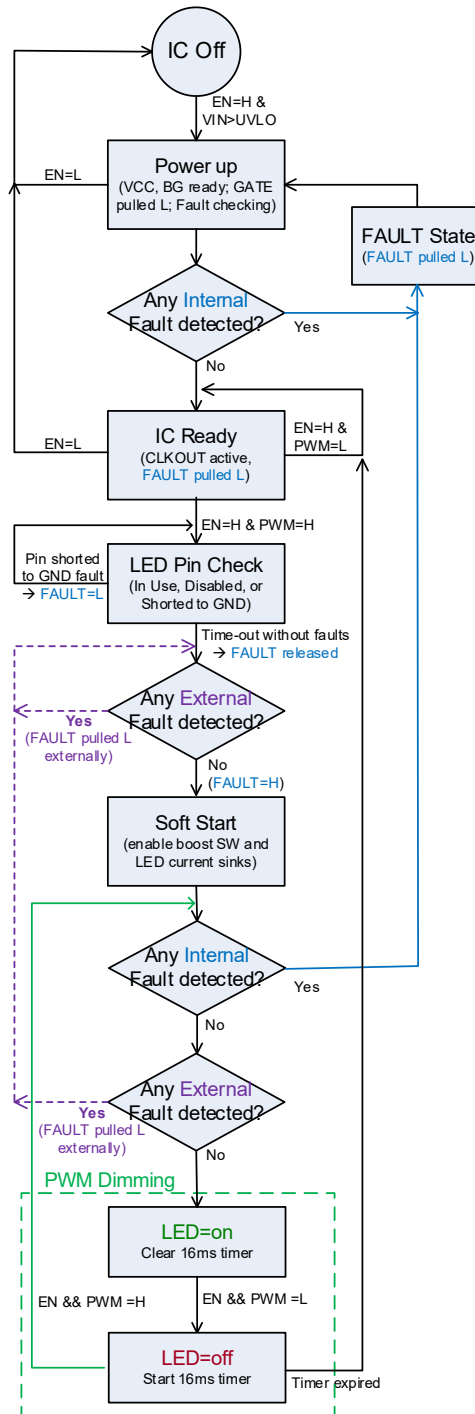

Figure 37: Simplified startup flow chart for A80601-1, showing responses to both Internal and External FAULT signals

LED String Partial-Short Detect

All LED current sink pins (LED1 to LED4) are designed to withstand the maximum output voltage, as specified in the Absolute Maximum Ratings table. This prevents the IC from being damaged if V_{OUT} is directly applied to an LED pin due to an output connector short.

In case of direct-short or partial-short fault in any LED string during operation, the LED pin with voltage exceeding V_{LESD} will be removed from regulation. This prevents the IC from dissipating too much power due to large voltage drop across the LED current sink.

Figure 38: A80601 Normal startup sequence showing voltage at LED1 and LED2 pins. $V_{IN} = 6\text{ V}$, output = $8 \times \text{WLED}$ in series, current = $4 \times 100\text{ mA}$

Figure 39: A80601 startup sequence when LED string#2 has a partial-short fault ($6 \times \text{WLED}$ instead of 8). As soon as LED2 pin rises above V_{LESDC} ($\sim 5\text{ V}$), the channel is disabled and $\text{FAULT} = \text{Low}$.

For A80601, the FAULT pin is pulled low in case any LED string is directly or partially shorted. The suspect LED string is disabled, while the rest of the LED strings continue to operate. FAULT pin is latched at low until it is reset by either $\text{EN} = \text{L}$ or $\text{PWM} = \text{L}$ for $>16\text{ ms}$

For A80601-1, all LED strings are turned off in case any LED string has detected a partial short. FAULT pin is latched at low until the IC is reset.

Figure 40: A80601-1 startup sequence when LED string#2 has a partial-short fault ($6 \times \text{WLED}$ instead of 8). As soon as LED2 pin rises above V_{LESDC} ($\sim 5\text{ V}$), the channel is disabled but FAULT remains High.

At least one LED pin must be at regulation voltage (below $\sim 1.2\text{ V}$) for the LED string partial-short detection to activate. In case all of the LED pins are above regulation voltage (this could happen when the input voltage rises too high for the LED strings), they will continue to operate normally.

Overvoltage Protection

The A80601 offers a programmable output overvoltage protection (OVP). The OVP pin has a threshold level of 2.5 V typical. Overvoltage protection is tripped when current into this pin exceeds $\sim 150 \mu\text{A}$. A resistor can be used to set the OVP threshold up to 40 V approximately. This is sufficient for driving 11 white LEDs in series.

The formula for calculating the OVP resistor is shown below:

$$\text{Equation 7: } R_{OVP} = (V_{OVP} - V_{OVP(th)}) / i_{OVP(th)}$$

where V_{OVP} is the desired OVP threshold, $V_{OVP(th)} = 2.5 \text{ V}$ typical, $i_{OVP(th)} = 150 \mu\text{A}$ typical.

To determine the desired OVP threshold, take the maximum LED string voltage at cold and add $\sim 10\%$ margin on top of it.

The OVP event is not a latched fault and, by itself, does not pull the FAULT pin to low. If the OVP condition occurs during a load dump, for example, the IC will stop switching but not shut down.

OVP condition is typically caused by an open LED fault, or disconnected output connector. It may be detected either at startup or during normal operation. This is explained separately below.

CASE 1: OVP AT STARTUP

During soft start period, the A80601 tries to boost V_{OUT} until it becomes high enough for all LED string to come into regulation. But if any LED string is open, V_{OUT} will eventually hit OVP. At this point, the A80601 will disable any LED string that is still not in regulation. The FAULT pin is pulled low and boost switching is stopped to allow V_{OUT} to fall. Once V_{OUT} falls below $\sim 97\%$ OVP, switching resumes to power the remaining LED strings.

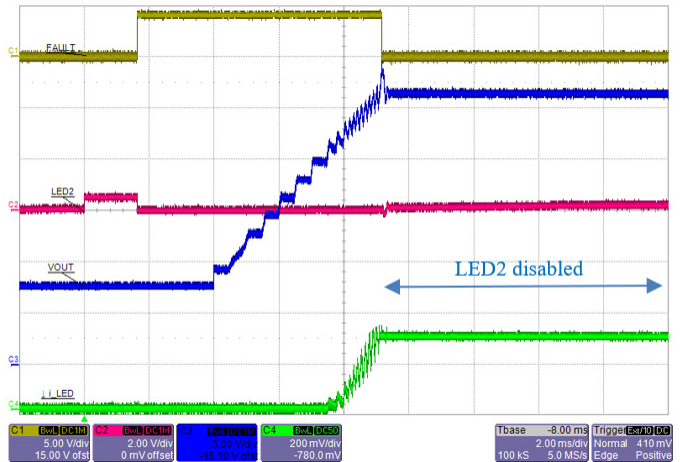

Figure 41: A80601 startup with LED2 string open. V_{OUT} hits OVP at $\sim 28 \text{ V}$ and LED2 is removed from regulation. FAULT pin goes Low but remaining LED strings continue to operate.

For A80601-1, all LED strings are disabled in case any string is not in regulation when V_{OUT} hits OVP. FAULT pin is pulled low and switching is stopped. The IC remains in latched off state until it is reset.

Figure 42: A80601-1 startup with LED2 string open. V_{OUT} hits OVP and all LED string are disabled. FAULT pin goes Low and IC remains latched off until reset.

CASE 2: OVP DURING NORMAL OPERATION

When one LED string becomes open during operation, current through its LED driver drops to zero. The A80601 responds by boosting the output voltage higher. When output reaches OVP threshold, the LED string without current is removed from regulation. The rest of LED strings continue to draw current and drain down V_{OUT} . Once V_{OUT} falls below $\sim 97\%$ OVP, boost will resume switching to power the remaining LED strings.

Figure 43: An open-LED string faults causes V_{OUT} to ramp up and trip OVP. The A80601 then disables the open LED string and continues with remaining strings.

The A80601-1, in contrast, will disable all LED strings in case any LED string becomes open. The IC remains in latched off state until it is reset.

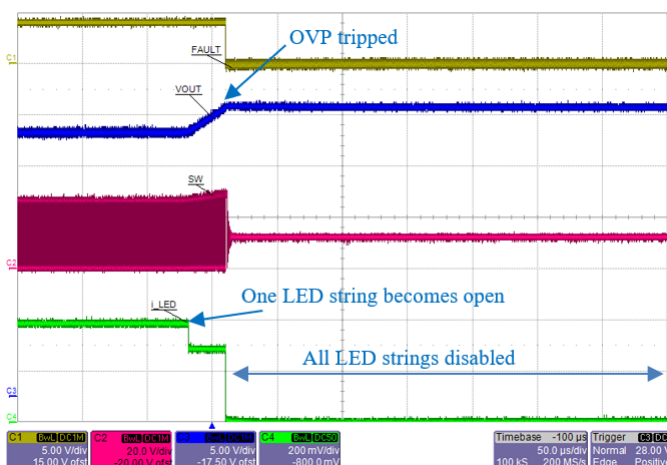

Figure 44: An open-LED string faults causes V_{OUT} to ramp up and trip OVP. The A80601-1 then disables all LED string and remains in latched off state until reset.

Boost Switch Overcurrent Protection

The external boost switch is protected with a cycle-by-cycle primary current limit. When the voltage sensed at CS pin exceeds $V_{CS(LIM1)}$ (typically 210mV), the existing switching cycle is truncated. That means the peak switching current is limited to:

$$\text{Equation 8: } i_{SW(LIM1)} = V_{CS(LIM1)} / R_{CS}$$

where R_{CS} is the sense resistor connected from source of boost MOSFET to power ground.

As an example, if $R_{CS} = 39 \text{ m}\Omega$, then $i_{SW(LIM1)} = 5.4 \text{ A}$ approximately.

The waveform below shows normal switching at $V_{IN} = 6 \text{ V}$, $V_{OUT} = \sim 26 \text{ V}$ and total LED current 800 mA. Average input current is around 4.5 A.

Figure 45: Normal 400 kHz switching waveform at $V_{IN} = 6 \text{ V}$. Red trace is the SW node voltage at 10 V/div. Green trace is the inductor current at 1 A/div.

When the input voltage is reduced further to 5.6 V, input current increases and peak switch current reaches 5.4 A. Overcurrent protection is tripped to limit the peak SW current.

Figure 46: When peak current through the inductor reaches ~5.4 A, overcurrent protection kicks in to truncate the present switching cycle.

There is also a secondary current sense limit $V_{CS(LIM2)}$, set at about 40% higher than the cycle-by-cycle current limit. It is to protect the external MOSFET from destructive current spikes in case the boost inductor or boost diode is shorted. Once this limit is tripped, the A80601 will immediately shut down and latch off.

Input Overcurrent Protection and Disconnect Switch

$$V_{IN} - V_{SENSE} = R_{SC} \times i_{SENSE} + R_{ADJ} \times i_{ADJ}$$

Figure 47: Optional input disconnect switch using a PMOSFET

The primary function of the input disconnect switch is to protect the system and the device from excessive input currents during a fault condition.

If the input current level goes above the preset threshold, the part will be shut down in less than 3 μ s. The FAULT pin is pulled Low and the IC remains in latched off state until it is reset. This feature prevents catastrophic failure in the system when there is a direct short from VOUT to GND (caused by a shorted output connector or cable, for example).

The waveform below illustrates the input overcurrent fault condition during startup. As soon as input OCP limit is reached, the part disables the gate of the disconnect switch Q1 and latches off.

Figure 48: Startup into an output shorted-to-GND fault. Input OCP is tripped when current (Green trace) exceeds ~6.5 A. PMOS Gate (Red) is turned off immediately and IC latches off.

During startup when Q1 first turns on, an inrush current flows through Q1 into the output capacitance. If Q1 turns on too fast (due to its low gate capacitance), the inrush current may trip input OCP limit. In this case, an external gate capacitance C_G is added to slow down the turn-on transition. Typical value for C_G is around 4.7 to 22 nF. Do not make C_G too large, since it also slows down the turn-off transient during a real input OCP fault.

Setting the Input Current Sense Resistor

The input disconnect switch threshold is typically 98 mV, measured between VIN and VSENSE pins when R_{ADJ} is 0 Ω. This threshold can be trimmed slightly using the R_{ADJ} resistor.

To avoid false tripping, the input disconnect switch overcurrent limit should be set higher than the boost switch cycle-by-cycle current limit. For example, the boost switch OCP is set at 5.4 A, so the input disconnect switch OCP may be set 25% higher at 6.75 A. The input current sense resistor is then calculated as below.

When R_{ADJ} is not used:

$$V_{IN} - V_{SENSE} = R_{SENSE} \times i_{SENSE} = 98 \text{ mV}$$

The desired sense resistor is $R_{SENSE} = 98 \text{ mV} / 6.75 \text{ A} = 14.5 \text{ m}\Omega$. But this is not a standard E-24 resistor value. Pick the closest lower value which is 13 mΩ.

When R_{ADJ} is used:

$$V_{IN} - V_{SENSE} = R_{SENSE} \times i_{SENSE} + R_{ADJ} \times i_{ADJ}$$

Therefore

$$\begin{aligned} R_{ADJ} &= [(V_{IN} - V_{SENSE}) - (R_{SENSE} \times i_{SENSE})] / i_{ADJ} \\ &= [98 \text{ mV} - 88 \text{ mV}] / 20 \mu\text{A} = 500 \Omega \end{aligned}$$

Pick the closest E-96 resistor value of 499 Ω.

Input UVLO

When V_{IN} rises above V_{UVLOrise} threshold, the A80601 is enabled. The IC is disabled when V_{IN} falls below V_{UVLOfall} threshold for more than 50 μs. This small delay is used to avoid shutting down because of momentary glitches in the input power supply.

Fault Protection During Operation

The A80601 constantly monitors the state of the system to determine if any fault conditions occur during normal operation. The response to a triggered fault condition is summarized in the table below. It is important to note that there are several points at which the A80601 monitors for faults during operation. The locations are input current, switch current, output voltage, switch voltage, and LED pins. Some of the protection features might not be active during startup to prevent false triggering of fault conditions.

The possible fault conditions that the part can detect include:

- Open LED Pin or open LED string
- Shorted or partially shorted LED string
- LED pin shorted to GND
- Open or shorted boost diode
- Open or shorted boost inductor
- VOUT short to GND
- SW shorted to GND
- ISET shorted to GND
- FSET shorted to GND
- Input disconnect switch drain shorted to GND

Note that some of these faults will not be protected if the input disconnect switch is not being used. An example of this is VOUT short to GND fault.

Table 5: A80601 Fault Mode Table

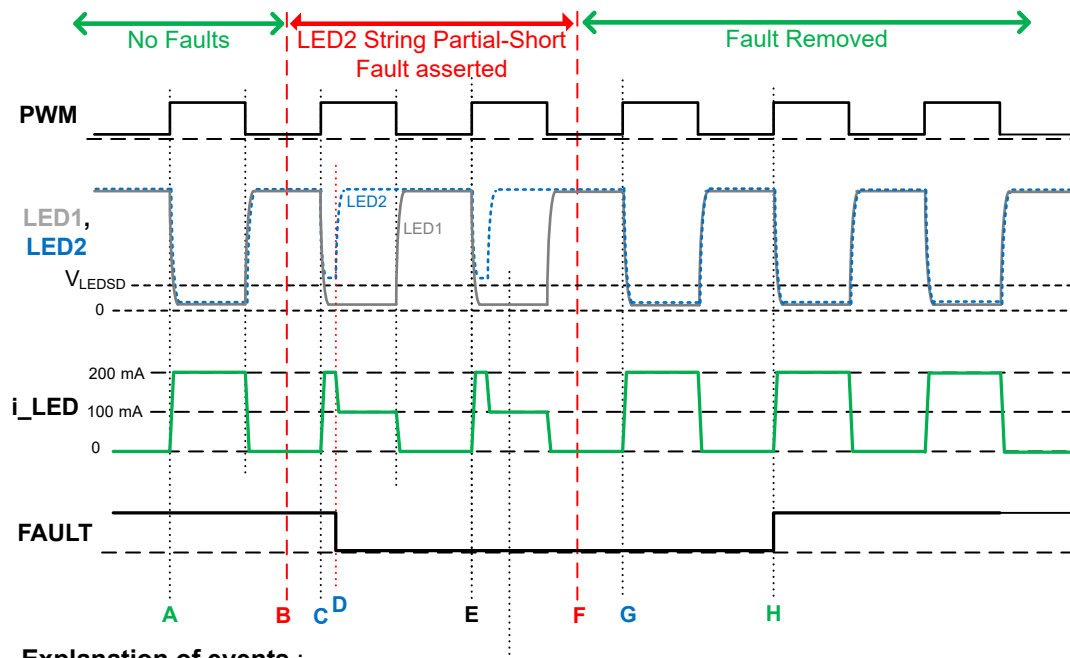

Fault Name	Type	Active	Fault Flag Set	Description	Boost Switch	Disconnect Switch	LED Sink drivers
Primary Switch Overcurrent Protection (Cycle-By-Cycle Current Limit)	Auto-restart	Always	NO	This fault condition is triggered when the SW current exceeds the cycle-by-cycle current limit, $I_{SW(LIM)}$. The present SW on-time is truncated immediately to limit the current. Next switching cycle starts normally.	Off for a single cycle	ON	ON
Secondary Switch Current Limit	Latched Off	Always	YES	When current through boost switch exceeds secondary SW current limit ($I_{SW(LIM2)}$) the device immediately shuts down the disconnect switch, LED drivers and boost. The Fault flag is set. To reset the fault the EN or PWM pin needs to be pulled low for ~16 ms.	OFF	OFF	OFF
Input Disconnect Current Limit	Latched Off	Always	YES	The device is immediately shut off if the voltage across the input sense resistor is above the $V_{SENSE(trip)}$ threshold. To reset the fault the EN or PWM pin must be pulled low for ~16 ms.	OFF	OFF	OFF
LEDx Pin Shorted to GND	Auto-restart	Startup	YES	If any of the LED pins is determined to be shorted to GND when PWM first goes high, soft-start process is halted. Only when the short is removed, then soft-start is allowed to proceed.	OFF	ON	OFF
LEDx Pin Open (One-Out-Continue option)	Auto-restart	Normal operation	YES	If an LED string is not getting enough current, the device will first respond by increasing the output voltage until OVP is reached. Any LED string that is still not in regulation will be disabled. The device will then go back to normal operation by reducing the output voltage to the appropriate voltage level.	ON	ON	OFF for open pins. ON for all others.
LEDx Pin Open (One-Out-All-Out option)	Latched	Normal operation	YES	If an LED string is not getting enough current, the device will first respond by increasing the output voltage until OVP is reached. If any LED string is still not in regulation, all LED strings will be disabled and the device latched off. To reset the fault the EN or PWM pin must be pulled low for ~16 ms.	OFF	OFF	OFF
ISET Short Protection	Auto-restart	Always	YES	Fault occurs when the ISET current goes above 150% of max current. The boost will stop switching and the IC will disable the LED sinks until the fault is removed. When the fault is removed, the IC will try to regulate to the preset LED current.	OFF	ON	OFF
FSET/SYNC Short Protection	Auto-restart	Always	YES	Fault occurs when the FSET current goes above 150% of max current. The boost will stop switching, Disconnect switch will turn off and the IC will disable the LED sinks until the fault is removed. When the fault is removed, the IC will try to restart with soft-start.	OFF	ON	OFF
Oversvoltage Protection	Auto-restart	Always	NO	Fault occurs when current into OVP pin exceeds $i_{OVP(th)}$ (typically 150 μ A). The IC will immediately stop switching but keep the LED drivers active, to drain down the output voltage. Once the output voltage decreases to ~94% OVP level, the IC will restart switching to regulate the output current.	STOP during OVP event.	ON	ON
Undervoltage Protection	Auto-restart	Always	YES	Device immediately shuts off boost and current sinks if the voltage at VOUT is below $V_{UVP(th)}$. This may happen if VOUT is shorted to GND, or boost diode is open before startup. It will auto-restart once the fault is removed.	OFF	ON	OFF
LED String Partial Short Detection (One-Out-Continue option)	Auto-restart	Always	YES	Fault occurs if an LED pin voltage exceeds V_{LEDSC} with its current sink in regulation, while at least one other LED pin is below ~1.2 V. This may happen when two or more LEDs are shorted within a string. The LED string exceeding the threshold will be disabled and removed from operation. Device will re-enable the LED string when its pin voltage falls below threshold, or at the next PWM = H.	ON	ON	OFF for shorted string, ON for all others.
LED String Partial Short Detection (One-Out-All-Out option)	Latched	Always	YES	If two or more LEDs are shorted within a string, all LED strings will be disabled and the device latched off. To reset the fault, EN or PWM pin must be pulled low for ~16 ms.	OFF	OFF	OFF
Overtemperature Protection	Auto-restart	Always	YES	Fault occurs when the die temperature exceeds the over-temperature threshold, typically 170°C. IC will restart after temperatures drops lower by T_{SDHYS}	OFF	OFF	OFF
V_{IN} UVLO	Auto-restart	Always	NO	Fault occurs when V_{IN} drops below $V_{UVLO(fail)}$. This fault resets all latched faults.	OFF	OFF	OFF

Table 5: A80601 Fault Mode Table (continued)

Fault Name	Type	Active	Fault Flag Set	Description	Boost Switch	Disconnect Switch	LED Sink drivers
FAULT pin pulled Low Externally (One-Out-Continue option)	Always ignored	Always ignored	No change	In One-Out-Continue mode (with unidirectional FAULT pin), external status of FAULT pin does not affect the operation of the IC in any way.	No change	No change	No change
FAULT pin pulled Low Externally (One-Out-All-Out option)	Auto-restart	Always	No change	In One-Out-All-Out mode (with bidirectional FAULT pin), if FAULT pin is externally pulled Low, the IC immediately shuts off its boost and LED current sinks. IC can only restart when external fault status is cleared AND there is no internal fault status pending. That means local latching faults cannot be cleared by externally forcing FAULT pin to High.	OFF	ON	OFF

LED String Partial-Short Detection in One-Out-Continue mode (A80601)

Explanation of events :

- A:** PWM goes High and all LED drivers operate normally. (For simplicity, assume only LED 1 and LED2 are in use, each sinking 100 mA.)
- B:** A partial-short fault is asserted to LED 2 string. Nothing happens yet since PWM = L.
- C:** At the next PWM = H, LED2 pin voltage stays above V_{LEDSD} while LED 1 pin is at regulation voltage.
- D:** After partial-short detection time ($\sim 2 \mu s$), LED2 string is disabled and FAULT pin pulled Low. LED1 string continues to operate.
- E:** At subsequent PWM = H, IC retries LED 1 but shuts it off again since the fault is still present. FAULT flag remains Low.
- F:** Partial Short fault is removed from LED 2 string. Nothing happens yet since PWM = L.
- G:** At the next PWM = H, IC retries LED 1 and it passes. But FAULT flag is not cleared
- H:** FAULT flag is cleared at the second PWM = H after Partial Short fault was removed.

APPENDIX A: DESIGN EXAMPLE

This section provides step-by-step instructions to select component values for an A80601 application.

For the purposes of this example, the following operating conditions are assumed:

- $V_{IN} = 12\text{ V}$ nominal (6 V min, 18 V max)
- Number of LED channels $n_c = 4$
- Number of series LEDs per channel $n = 7$
- LED current per channel $I_{LED} = 150\text{ mA}$
- LED forward drop $V_f = 3.2\text{ V}$ max at cold
- Switching frequency $f_{SW} = 2.15\text{ MHz}$
- Dithering modulation frequency $f_{DITH} = 1\text{ kHz}$
- Dithering frequency range $\Delta f_{SW} = \pm 5\%$
- Max ambient temperature $T_{A(max)} = 65^\circ\text{C}$
- PWM dimming frequency $f_{PWM} = 200\text{ Hz}$

Step 1: Program the Switching Frequency from Equation 1:

$$f_{SW} = 21.5 / (R_{FSET} + 0.2)$$

Therefore

$$R_{FSET} - 0.2 = 21.5 / f_{SW}$$

where f_{SW} is in MHz and R_{FSET} is in k Ω .

Substitute $f_{SW} = 2.15\text{ MHz}$ to get $R_{FSET} = 9.8\text{ k}\Omega$ (pick 10 k Ω).

Step 1a: Program the Dithering Modulation Frequency from Equation 2:

$$f_{DITH} (\text{kHz}) = 25 / C_{DITH} (\text{nF})$$

Substitute $f_{DITH} = 1\text{ kHz}$ to get $C_{DITH} = 25\text{ nF}$ (pick 22 nF).

Step 1b: Select Dithering Range from Equation 3:

$$\Delta f_{SW} \text{ Range } (\pm\%) = 20 \times R_{FSET} / R_{DITH}$$

Substitute Range = 5 and $R_{FSET} = 10\text{ k}\Omega$ to get $R_{DITH} = 40\text{ k}\Omega$ (pick 40.2 k Ω). The switching frequency now linearly sweeps between 2.04 and 2.26 MHz.

Step 2: Determine the LED current set Resistor R_{ISET} from Equation 4:

$$R_{ISET} = (V_{ISET} \times A_{ISET}) / I_{LED}$$

Substitute $V_{ISET} = 0.985\text{ V}$, $A_{ISET} = 1466$, and $I_{LED} = 150\text{ mA}$ to get $R_{ISET} = 9.63\text{ k}\Omega$ (pick 9.53 k Ω).

Step 3: Determining the OVP resistor according to Equation 6:

$$R_{OVP} = (V_{OVP} - V_{OVP(th)}) / i_{OVP(th)}$$

The nominal output voltage is:

$$V_{OUT_nom} = n \times V_f + V_{REG}$$

where V_{REG} is the LED pin regulation voltage. Substitute $n = 7$, $V_f = 3.2\text{ V}$ and $V_{REG} = 0.85\text{ V}$ to get $V_{OUT_nom} = 23.25\text{ V}$.

Set the OVP threshold voltage approximately 10% higher, to account for error margin and component tolerances:

$$V_{OVP} = V_{OUT_nom} \times 1.1 = 25.6\text{ V}$$

The OVP resistor is therefore:

$$\begin{aligned} R_{OVP} &= (25.6\text{ V} - 2.5\text{ V}) / 150\ \mu\text{A} \\ &= 154\text{ k}\Omega \text{ (pick } 154\text{ k}\Omega) \end{aligned}$$

Step 3a: Check to ensure the maximum boost duty cycle is sufficient to achieve the required conversion ratio.

$$D_{MAX(boost)} = 1 - t_{SW(off)} \times f_{SW(max)}$$

where $t_{SW(off)}$ is the worst-case minimum SW on-time, and $f_{SW(max)}$ is the maximum switching frequency with dithering.

Substitute $t_{SW(off)} = 100\text{ ns}$ and $f_{SW(max)} = 2.26\text{ MHz}$ to get $D_{MAX(boost)} = 0.774$.

Theoretical maximum output voltage at the lowest input voltage is:

$$V_{OUT(max)} = V_{IN(min)} / (1 - D_{MAX(boost)}) - V_D$$

where V_D is the forward drop of boost Schottky diode.

Substitute $V_{IN(min)} = 6\text{ V}$, $D_{MAX(boost)} = 0.774$, and $V_D = 0.4\text{ V}$ to get $V_{OUT(max)} = 26.15\text{ V}$.

Theoretical $V_{OUT(max)}$ has to be greater than V_{OVP} . If this is not the case, then switching frequency of the boost converter must be reduced to meet the maximum duty cycle requirement.

Step 4 – Inductor selection: The inductor must be chosen based on ripple current requirement. In most applications due to stringent EMI requirements, the system also needs to operate in continuous conduction mode (CCM) throughout the whole input voltage range. A simple guideline is to start with 30% peak-to-peak ripple current at nominal input and output voltages.

Step 4a: Determine the Boost Duty Cycle:

$$D = 1 - V_{IN} / (V_{OUT} + V_D)$$

For nominal operation, substitute $V_{IN_nom} = 12\text{ V}$, $V_{OUT_nom} = 23.25\text{ V}$ and $V_D = 0.4\text{ V}$ to get $D_{nom} = 0.493$.

Step 4b: Calculate the nominal Input Current based on estimated efficiency:

$$i_{IN} = V_{OUT} \times i_{OUT} / (V_{IN} \times \eta)$$

where η = efficiency of the converter (typically in the 85% to 90% range).

For nominal operation, substitute $V_{OUT} = 23.25\text{ V}$, $i_{OUT} = 0.6\text{ A}$, $V_{IN} = 12\text{ V}$, and $\eta = 0.9$ to get $i_{IN} = 1.29\text{ A}$.

Step 4c: Select Boost Inductance based on 30% Ripple Current.

For nominal operation, $\Delta i_L = 0.3 \times i_{IN} = 0.39\text{ A}$.

$$\Delta i_L = t_{ON} \times V_{IN} / L = D \times V_{IN} / (f_{SW} \times L)$$

Therefore:

$$L = D \times V_{IN} / (f_{SW} \times \Delta i_L)$$

Substitute $D_{nom} = 0.493$, $V_{IN_nom} = 12\text{ V}$, and $f_{SW} = 2.15\text{ MHz}$ to get $L = 7.1\text{ }\mu\text{H}$ (pick $6.8\text{ }\mu\text{H}$).

STEP 4d: Determine the maximum and minimum input current to the system. The maximum current determines the inductor's saturation current rating. The minimum current determines its critical inductance.

Maximum input current occurs at minimum V_{IN} and maximum V_{OUT} (OVP).

$$i_{IN_max} = V_{OVP} \times i_{OUT} / (V_{IN_min} \times \eta)$$

Substitute $V_{OVP} = 25.6\text{ V}$, $V_{IN_min} = 6\text{ V}$, and $\eta = 0.85$ to get $i_{IN_max} = 3.01\text{ A}$.

Peak inductor current:

$$i_{L_peak} = i_{IN_max} + \Delta i_L / 2$$

At minimum $V_{IN} = 6\text{ V}$, $D = 0.769$, $\Delta i_L = 0.316\text{ A}$, and so $i_{L_peak} = 3.01 + 0.316 / 2 = 3.17\text{ A}$. Therefore, the inductor should have a saturation current of at least 3.8 A (20% higher than i_{L_peak}).

Minimum input current occurs at maximum V_{IN} and nominal V_{OUT} .

$$i_{IN_min} = V_{OUT_nom} \times i_{OUT} / (V_{IN_max} \times \eta)$$

Substitute $V_{OUT_nom} = 23.25\text{ V}$, $V_{IN_max} = 18\text{ V}$, and $\eta = 0.9$ to get $i_{IN_min} = 0.865\text{ A}$.

At maximum $V_{IN} = 18\text{ V}$, $D = 0.239$, $\Delta i_L = 0.294\text{ A}$, and so $i_{L_valley} = 0.865 - 0.294 / 2 = 0.718\text{ A}$. Therefore the converter operates in CCM throughout the input voltage range.

Step 5: To verify that there is sufficient slope compensation for the inductor chosen. The A80601 generates a variable internal Slope Comp according to f_{SW} and V_{IN} .

- If V_{IN} is between 9 V and 15 V :
 $SC = 3 \times f_{SW} \times V_{IN} / 12$
- If $V_{IN} < 9\text{ V}$:
 $SC = 3 \times f_{SW} \times 9 / 12$
- If $V_{IN} > 15\text{ V}$:
 $SC = 3 \times f_{SW} \times 15 / 12$

where f_{SW} is in MHz and SC is in A/ μs .

For example, at $f_{SW} = 2.15\text{ MHz}$ and $V_{IN} = 6\text{ V}$, $SC = 4.74\text{ A}/\mu\text{s}$

The falling slope of inductor current is given as:

$$di_L/dt = -\Delta i_L / t_{OFF} = -\Delta i_L \times f_{SW} / (1 - D)$$

Based on equations from previous section, at $V_{IN} = 6\text{ V}$ and $V_{OUT(OVP)} = 25.6\text{ V}$, $D = 0.769$ and $\Delta i_L = 0.316\text{ A}$. Therefore $|di_L/dt| = 2.94\text{ A}/\mu\text{s}$, which is slower than the internal slope. That means there is sufficient slope compensation.

In case the negative slope of inductor current is faster than the internal slope comp, a higher inductance value must be used.

Step 6: Select External Boost Switch MOSFET.

Refer to Appendix B for more details on how to select the external boost MOSFET. For this example, the MOSFET picked is NVD5867NL with the following key parameters:

- Breakdown voltage $V_{(BD)DSS} = 60\text{ V}$ min
- On-resistance $R_{DS(on)} = 50\text{ m}\Omega$ max at $V_{GS} = 4.5\text{ V}$
- Total Gate Charge $Q_G = 10\text{ nC}$ for $V_{GS} = 0$ to 6.5 V

Step 7: Select boost switch current sense resistor.

From Equation 8:

$$R_{CS} = V_{CS(LIM1)} / i_{SW(LIM1)}$$

From previous section, $i_{L_peak} = 3.17\text{ A}$ at min V_{IN} and max V_{OUT} . Set the cycle-by-cycle SW current limit at least 20% higher, which means $\sim 3.8\text{ A}$. Therefore:

$$R_{CS} = 210\text{ mV} / 3.8\text{ A} = 55\text{ m}\Omega$$

Pick a standard E-12 resistor value of $47\text{ m}\Omega$. This gives cycle-by-cycle current limit of $i_{SW(LIM1)} = 4.5\text{ A}$.

Step 8: Choosing the input disconnect switch components.

Set the input disconnect switch current limit at least 20% above the SW cycle-by-cycle current limit:

$$i_{SENSE} = 3.8 A \times 1.2 = 4.56 A$$

$$R_{SC} = V_{SENSETRIP} / i_{SENSE} = 21.5 m\Omega$$

Pick the closest lower resistance value from E-24 series, which is 20 mΩ.

$$R_{ADJ} = [V_{SENSETRIP} - (R_{SC} \times i_{SENSE})] / i_{ADJ} = 340 \Omega$$

Select the input disconnect switch P-MOSFET based on its drain-source breakdown voltage and on-resistance.

The SQJ459EP can be used in this case. It has $V_{DS} = -60 V$ and $R_{DS(ON)} = 24 m\Omega$ at $V_{GS} = -4.5 V$.

Step 9: Select the switching diode.

A Schottky barrier diode (SBD) is typically selected based on its voltage and current ratings:

- The reverse voltage rating must be higher than the maximum voltage stress, which is equal to the OVP threshold in this case.
- The average forward current rating must be higher than the total LED current. The peak current through diode is given as:

$$i_{D_peak} = i_{L_peak} = i_{IN_max} + \Delta i_L / 2$$

From previous calculation at minimum V_{IN} , $i_{L_peak} = 3.17 A$. However, during transient, this current could reach cycle-by-cycle SW current limit, $i_{SW(LIM)}$.

Another critical parameter is the diode's reverse leakage current at hot. This is especially important when using PWM dimming. During PWM off time, the boost converter is not switching, so voltage at output capacitor decays due to leakage current. This increases output ripple voltage, which may generate audible noise from ceramic capacitors.

Make sure to verify the diode's reverse current at hot (such as 125°C) and at the nominal V_{OUT} . As a general guideline, look for a diode with leakage of 100 μA or less. If necessary, consider using a diode with higher voltage rating (such as 100 V instead of 50 V). Doing so can significantly reduce the leakage current at nominal V_{OUT} .

For this design example, a 100 V, 3 A Schottky diode SS3H10 is selected. It has a very low $i_R = 50 \mu A$ at $T_J = 125^\circ C$ and $V_R = 30 V$.

Step 10: Selection of output capacitors.

The use of multilayer ceramic capacitor (MLCC) is recommended. MLCC has extremely low ESR, which is necessary to reduce output switching ripple for boost converter. In addition, the total output capacitance needs to be sufficient to reduce output droop during PWM dimming operation.

The biggest contributing factors for total output capacitance are PWM off-time and leakage current (i_{LK}). This current is mainly due to the reverse current of switching diode, plus a small/negligible leakage current into the OVP pin.

In this design example, the PWM dimming frequency is 200 Hz with minimum duty cycle of 0.01%. So the maximum PWM off-time is essentially $t_{OFF} = 5 ms$. A typical goal is to keep the output voltage variation at 250 mV or less, so that no audible hum can be heard.

$$\Delta V_{OUT} = t_{OFF} \times i_{LK} / C_{OUT}$$

Therefore:

$$C_{OUT} = t_{OFF} \times i_{LK} / \Delta V_{OUT}$$

Substitute $t_{OFF} = 5 ms$, $i_{LK} = 110 \mu A$, and $\Delta V_{OUT} = 0.25 V$ to get $C_{OUT} = 2.2 \mu F$.

A major problem with multilayer ceramic capacitor (MLCC) is that its actual capacitance drops with respect to DC bias. For example, the capacitance of a 4.7 μF, 50 V, 0805 MLCC may be derated by 80% when it is biased at 25 V. That means its real capacity is less than 1 μF in actual application.

MLCC with larger physical size and higher voltage rating typically suffers less derating problem. For example, a 4.7 μF, 50 V, 1210 MLCC may retain 3.3 μF of capacitance at 25 V. This is shown in the table below:

Part Number	Package	Rated Capacitance at 0 V (μF)	Derating at 25 V	Actual Capacitance at 25 V (μF)
GRM21BC71H475KE11	0805	4.7	-80%	0.94
GRM31CR71H475MA12	1206	4.7	-45%	2.59
GRM32ER71H475KA88	1210	4.7	-30%	3.29

Step 11: Selection of input capacitor.

A combination of MLCC and electrolytic capacitor is recommended. The MLCC provides low ESR to reduce input switching ripple. The electrolytic capacitor provide larger capacitance to stabilize input voltage during PWM dimming operation.

A good rule of thumb is to set the input voltage ripple ΔV_{IN} to be 1% of the minimum input voltage. The minimum input capacitor requirements are as follows.

$$C_{IN} = \Delta i_L / (8 \times f_{SW} \times \Delta V_{IN})$$

Substitute $\Delta i_L = 0.316 A$ at $V_{IN} = 6 V$ (from step 4d), $\Delta V_{IN} = 0.06 V$, and $f_{SW} = 2.15 MHz$ to get $C_{IN} = 0.306 \mu F$. Due to the DC bias derating, the actual MLCC selected should be rated 1 μF or higher.

A80601 and A80601-1

High Power LED Driver with Pre-Emptive Boost for Ultra-High Dimming Ratio and Low Output Ripple

A much larger input capacitance is required to provide the inrush current during PWM dimming operation. The exact requirement depends on many external factors, such as length of power cables and response time of the power supply. As a first-order estimate: assuming the power supply takes 25 μ s to respond, and the input capacitor must keep the V_{IN} drip under 0.2 V while input current ramps up from zero to full load. The following is needed:

$$C_{IN} = i_{IN} \times t_{PS} / (8 \times \Delta V_{IN})$$

Substitute $i_{IN} = 3.01$ A at $V_{IN} = 6$ V (from step 4d), $\Delta V_{IN} = 0.2$ V and $t_{PS} = 25$ μ s to get $C_{IN} = 47$ μ F. Use an electrolytic capacitor of 47 μ F in parallel with the MLCC.

The following schematic diagram shows calculated component values from the design example:

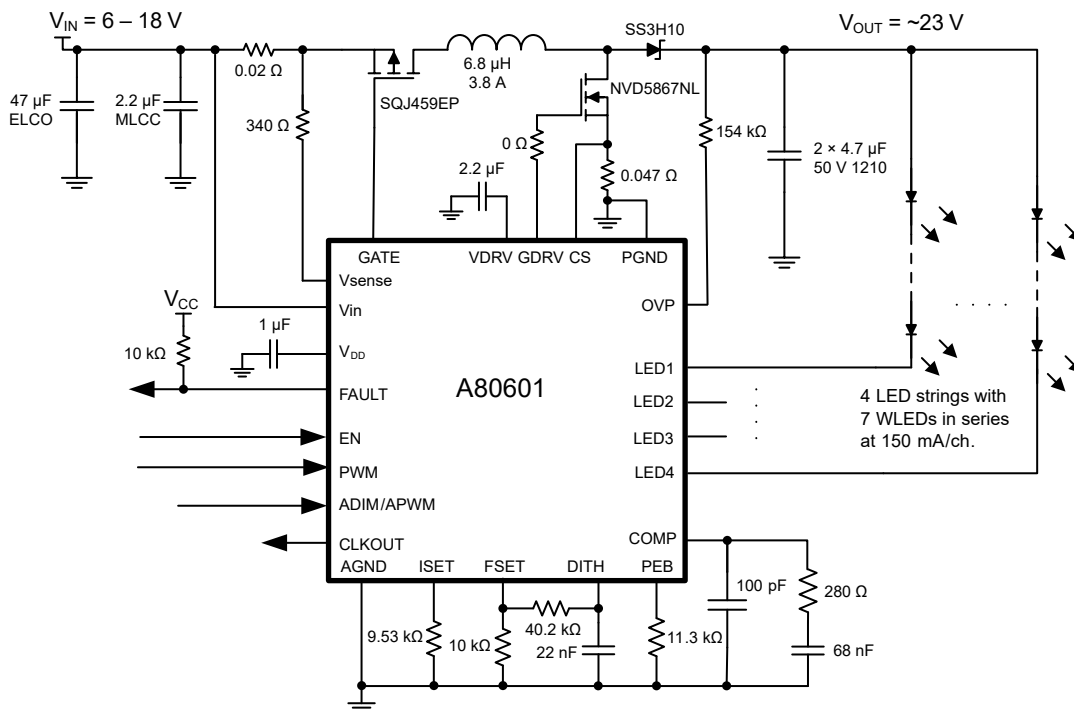

Figure 50: A80601 boost schematic for the design example

APPENDIX B: EXTERNAL MOSFET SELECTION GUIDE

The A80601 drives an external MOSFET for the boost stage. This solution provides maximum flexibility in delivering a wide range of output voltage and current for different LED panels, compared to controllers with built-in boost switches. On the other hand, care must be taken in selection of external MOSFET, to ensure optimal tradeoff between component size, efficiency, and cost. Primary Parameters to consider include the following.

BREAKDOWN VOLTAGE

Pick the device with “Drain to Source Breakdown Voltage” at least 20% higher than the maximum possible SW voltage.

- For boost configuration, $V_{SW} = V_{OUT} + V_F$; where V_F = boost diode forward drop.
The A80601 has a maximum V_{OUT} of 40 V. Therefore, the MOSFET should be rated 50 V or higher.
- For SEPIC configuration, $V_{SW} = V_{IN} + V_{OUT} + V_F$.
Note that V_{IN} can be as high as 40 V during load-dump conditions. The breakdown voltage needs to be increased accordingly.

GATE THRESHOLD VOLTAGE

The device must be fully enhanced by the time $V_{GS} = 5$ V. Note that this is not the same as “Gate to Source Threshold Voltage” in most MOSFET datasheets, which is typically specified at very small current such as 250 μ A. A more reliable way is to consult the “Gate Charge Characteristics” chart of the device, and make sure that the ‘plateau’ occurs well before V_{GS} reaches 5 V. See example from datasheet of one potential candidate:

Figure 51: Gate Charge vs. Gate-Source Voltage for an example MOSFET. Note plateau at $V_{GS} = 4.2$ V approximately.

ON-RESISTANCE

Device with lower $R_{DS(ON)}$ can directly reduce the conduction loss of the boost converter. This is especially important when the output power is high and input supply voltage is low. Note that most datasheets typically highlight this parameter at $V_{GS} = 10$ V and $T_J = 25^\circ\text{C}$. It is important to examine how $R_{DS(ON)}$ varies with gate voltage and temperature, as shown in the following charts:

Figure 52: Chart showing On-Resistance varies with Drain Current and Gate Voltage.

Figure 53: Normalized On-Resistance vs. Junction Temperature at $V_{GS} = 10$ V. Note that resistance increases by 100% when temperature rises from 25°C to 150°C .

THERMAL RATING

The thermal resistance ($R_{\theta JA}$) is primarily determined by the device's physical size. If the thermal resistance of the device is too high, or if there is insufficient heat dissipation on the PCB, the device may enter thermal run-away situation and burn itself out. For most medium-power (10-30 W) applications, a DPAK device is generally sufficient. For high-power (>50 W) applications, a D²PAK device may be required. Depending on power loss, additional heat sink can be mounted to improve the heat dissipation from the PCB.

GATE CHARGE

As mentioned earlier, lower $R_{DS(on)}$ is desired to reduce conduction loss. But devices with lower $R_{DS(on)}$ typically also have higher gate charge (Q_G), which can lead to higher switching loss. This is especially important when switching at high frequency (such as 2 MHz) and with high output voltage. Higher gate charge also results in higher gate driver current and hence higher power loss for the controller IC.

The A80601 uses an LDO to supply the driver voltage (V_{DRV}), which has a current limit of 36 mA typical. Average gate driver current is:

$$i_{V_{DRV}} = f_{SW} \times Q_G$$

If the MOSFET selected has $Q_G = 27$ nC, for example, then the highest switching frequency is limited to 1.33 MHz. See the following chart for relation between maximum switching frequency and MOSFET gate charge:

Figure 54: Maximum Switching Frequency vs. Gate Charge (to keep average V_{DRV} current under 36 mA).

On the other hand, selecting a device with very low Q_G may cause excessive voltage spikes at SW node due to high dV/dt . In this case, a snubber circuit can be added to dampen the ringing. The switching speed can be slowed down by adding a series gate resistance (such as 1-5 ohm) between the driver and the device. The downside of doing this is higher switching losses.

Figure 55: Gate Charge vs. Gate-Source Voltage chart for a suitable MOSFET (NVD5867NL). Note that its plateau is at ~3.5 V, and its total gate charge is about 10 nC as V_{GS} ramps up from 0 to 6.5 V.
