

MPQ4313

45V, 3A, Low I_Q Synchronous Step-Down Converter with Frequency Spread Spectrum, AEC-Q100 Qualified

DESCRIPTION

The MPQ4313 is a frequency-programmable, synchronous, step-down switching regulator with integrated internal high-side and low-side power MOSFET. It provides up to 3A of highly efficient output, with current mode control for fast loop response.

The wide 3.3V to 45V input voltage range accommodates a variety of step-down applications in an automotive input environment. A 1.7µA shutdown mode quiescent current allows the part to be used in battery-powered applications. High power conversion efficiency over a wide load range is achieved by scaling down the switching frequency in light-load conditions to reduce the switching and gate driver losses.

An open-drain power good signal indicates whether the output is within 95% to 105% of its nominal voltage.

Frequency foldback helps prevent inductor current runaway during start-up. Thermal shutdown provides reliable, fault-tolerant operation. High-duty cycle and low-dropout mode are provided for automotive cold crank conditions.

The MPQ4313 is available in a QFN-20 (4mmx4mm) package.

MPQ4313 FAMILY VERSIONS

Part Number	Output Current	Package Options
MPQ4312	2A	QFN-20 (4mmx4mm) WF ⁽¹⁾
MPQ4313	3A	
MPQ4314	4A	
MPQ4315	5A	
MPQ4316	6A	
MPQ4317	7A	

Note:

1) "WF" means wettable flank.

FEATURES

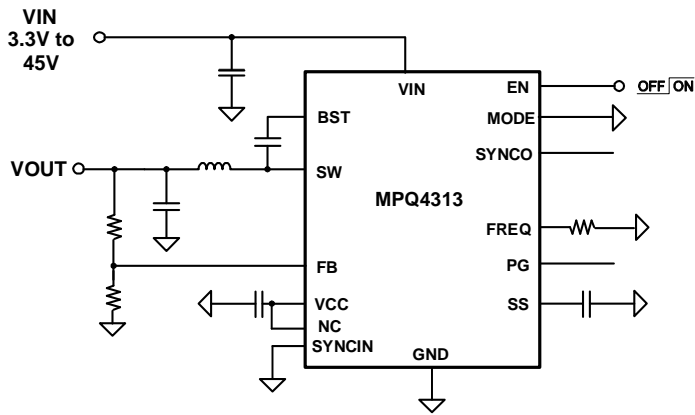

- Wide 3.3V to 45V Operating Range
- 3A Continuous Output Current
- 1.7µA Low Shutdown Supply Current
- 18µA Sleep Mode Quiescent Current
- Internal 48mΩ High-Side and 20mΩ Low-Side MOSFETs
- 350kHz to 1000kHz Programmable Switching Frequency for Car Battery Applications
- Switching Frequency Can Be Synchronized to External Clock
- Out-of-Phase Synchronized Clock Output
- 3.3V, 5V Fixed Output Options
- Frequency Spread Spectrum (FSS) for Low EMI
- Symmetric V_{IN} for Low EMI
- Power Good Output
- External Soft Start
- 100ns Minimum On Time
- Selectable Advanced Asynchronous Mode (AAM) or Forced Continuous Conduction Mode (FCCM)
- Low-Dropout Mode
- Hiccup Over-Current Protection
- Available in a QFN-20 (4mmx4mm) Package
- Available in a Wettable Flank Package
- Available in AEC-Q100 Grade 1

APPLICATIONS

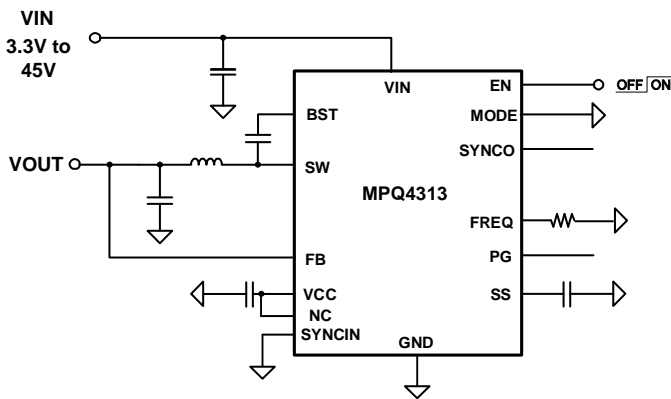

- Automotive Infotainment
- Automotive Clusters
- Advanced Driver Assistance Systems
- Industrial Power Systems

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS", the MPS logo, and "Simple, Easy Solutions" are trademarks of Monolithic Power Systems, Inc. or its subsidiaries.

PACKAGE REFERENCE

PIN FUNCTIONS

Pin #	Name	Description
1	MODE	AAM or FCCM selection pin. Pull this pin high to put the part in forced continuous conduction mode (FCCM), and pull it low for AAM at light-load. Do not leave this pin floating.
2	SYNCIN	SYNC input. Apply a 350kHz to 1000kHz clock signal to this pin to synchronize the internal oscillator frequency to the external clock. SYNCIN has an internally high impedance. Do not float the pin under any circumstances. If used, ensure that the external sync clock has adequate pull-up and pull-down capability. It is recommended to place a $\leq 51\text{k}\Omega$ resistor between SYNCIN and GND in case the external sync clock's pull-down capability is insufficient or SYNCIN enters a high-impedance state.
3, 12	VIN	Input supply. VIN supplies power to all the internal control circuitry and the power switch connected to SW. A decoupling capacitor to ground is recommended to be placed close to VIN to minimize switching spikes.
4, 5, 10, 11	PGND	Power ground.
6	BST	Bootstrap. BST is the positive power supply for the high-side MOSFET driver connected to SW. Connect a bypass capacitor between this BST and SW.
7, 8	SW	Switch node. SW is the output of the internal power switch.
9	EN	Enable. Pull this pin below the specified threshold (0.85V) to shut down the chip. Pull it above the specified threshold (1V) to enable the chip.
13	SYNCO	SYNC output. Output a clock signal to be 180° out-of-phase from the internal oscillator signal or to be opposite from the clock signal applied at the SYNCIN pin. Leave this pin floating if not used.
14	PG	Power good indicator. The output of PG is an open drain; if this pin is used, a pull-up resistor to the power source is required. It goes high if the output voltage is within 95% to 105% of the nominal voltage, and goes low if the output voltage is above 106.5% or below 93.5% of the nominal voltage.
15	NC	Not connected. Connect this pin to the VCC pin or V _{OUT} , which must be no less than 3V. Do not float this pin.
16	VCC	Bias supply. This supplies power to the internal control circuit and gate drivers. A decoupling capacitor to ground must be placed close to this pin. To calculate the size of this capacitor, see the Setting the VCC Capacitor section on page 31.
17	AGND	Analog ground.
18	FB	Feedback input. For the adjustable output version, connect FB to the center point of the external resistor divider from the output to AGND to set the output voltage. The feedback threshold voltage is 0.815V. Place the resistor divider as close to FB as possible. For the fixed output version, connect the FB pin directly to the output. Avoid placing vias on the FB traces.
19	SS	Soft-start input. Place a capacitor from SS to GND to set the soft-start period. The MPQ4313 sources 6 μ A from SS to the soft-start capacitor at start-up. As the SS voltage rises, the feedback threshold voltage increases to limit inrush current during start-up.
20	FREQ	Switching frequency program. Connect a resistor from this pin to ground to set the switching frequency. Follow the f _{SW} vs. R _{FREQ} curve in TYPICAL PERFORMANCE CHARACTERISTICS (TPC) section to set the frequency.

ABSOLUTE MAXIMUM RATINGS ⁽²⁾

VIN, EN	-0.3V to +50V
SW	-0.3V to V _{IN(MAX)} + 0.3V
BST	V _{SW} + 6V ⁽³⁾
All other pins	-0.3V to +5.5V
Continuous power dissipation (T _A = 25°C) ⁽⁴⁾ ⁽⁶⁾	
QFN-20 (4mmx4mm)	5.4W
Junction temperature	150°C
Lead temperature	260°C

QFN-20 (4mmx4mm)		
JESD51-7 ⁽⁵⁾	44.....	9....°C/W
EVQ4313-R-00A ⁽⁶⁾	23.....	2.5...°C/W

Notes:

- 2) Exceeding these ratings may damage the device.
- 3) Rated under room temperature.
- 4) The maximum allowable power dissipation is a function of the maximum junction temperature T_J (MAX), the junction-to-ambient thermal resistance θ_{JA}, and the ambient temperature T_A. The maximum allowable continuous power dissipation at any ambient temperature is calculated by P_D (MAX) = (T_J (MAX) - T_A) / θ_{JA}. Exceeding the maximum allowable power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- 5) Measured on JESD51-7, a 4-layer PCB. The values given in this table are only valid for comparison with other packages and cannot be used for design purposes. These values were calculated in accordance with JESD51-7, and simulated on a specified JEDEC board. They do not represent the performance obtained in an actual application.
- 6) Measured on standard MPS EVB, a 2oz copper thickness, 4-layer PCB (9cmx9cm).

ELECTRICAL CHARACTERISTICS

V_{IN} = 12V, V_{EN} = 2V, T_J = -40°C to +125°C, typical values are at T_J = 25°C, unless otherwise noted.

Timing Sequence Diagram

Figure 3: Timing Sequence Diagram

OPERATION

The MPQ4313 is a synchronous, step-down switching regulator with integrated, internal high-side and low-side power MOSFETs. It provides 3A of highly efficient output with current mode control.

The MPQ4313 features a wide input voltage range, programmable switching frequency, external soft start, and precision current limiting. The device's very low operational quiescent current makes it suitable for battery-powered applications.

PWM Control

At moderate to high output currents, the MPQ4313 operates in fixed-frequency, peak current control mode to regulate the output voltage. A PWM cycle is initiated by the internal clock. At the rising edge of the clock, the high-side power MOSFET (HS-FET) turns on and remains on until its current reaches the value set by the internal COMP voltage (V_{COMP}). Once the HS-FET is on, it remains on for at least 100ns.

When the HS-FET is off, the low-side MOSFET (LS-FET) turns on immediately and remains on until the next cycle starts. Once the LS-FET is on, it remains on for at least 80ns before the next cycle starts.

If the current in the HS-FET does not reach the COMP set current value within one PWM period, the HS-FET remains on, saving a turn-off operation. The HS-FET is forced off if the on time lasts about 10µs and V_{COMP} is not reached.

Light-Load Operation

In light-load conditions, the MPQ4313 can work in one of two different operation modes by setting the MODE pin to a different status (see Figure 4).

The MPQ4313 works in forced CCM (FCCM) when the CCM pin is pulled above 1.8V. In this mode, the device works with a fixed frequency from no-load to full-load. The advantage of FCCM is the controllable frequency and lower output ripple at light-load.

The MPQ4313 works in asynchronous advanced mode (AAM) when the MODE pin is pulled below 0.4V. AAM optimizes efficiency during light-load and no-load conditions.

When AAM is enabled, the MPQ4313 first enters nonsynchronous operation as long as the inductor

current approaches zero at light-load. If the load is further decreased or there is no load that makes the internal COMP voltage (V_{COMP}) decrease to the set value, the MPQ4313 enters AAM. In AAM, the internal clock is reset every time V_{COMP} crosses the set threshold, and the crossover time is taken as the benchmark of the next clock. When the load increases and V_{COMP} exceeds the set value, the operation mode is DCM or CCM, which has a constant switching frequency.

Figure 4: AAM and FCCM

Error Amplifier

The error amplifier compares the FB pin voltage with the internal reference (0.815V) and outputs a current proportional to the difference between the two. This output current is then used to charge the compensation network to form V_{COMP} , which controls the power MOSFET current.

During operation, the minimum V_{COMP} is clamped to 0.9V and its maximum is clamped to 2.0V. In shutdown mode, COMP is pulled down to GND internally.

Internal Regulator VCC

Most of the internal circuitry is powered by the internal 4.9V VCC regulator. This regulator takes V_{IN} as the input and operates in the full V_{IN} range. When V_{IN} exceeds 4.9V, VCC is in full regulation. When V_{IN} falls below 4.9V, the output VCC degrades.

Bootstrap Charging

The bootstrap capacitor is charged and regulated to about 5V by the dedicated internal bootstrap regulator. When the voltage between the BST and SW nodes is below its regulation, a PMOS pass transistor connected from VCC to BST turns on to charge the bootstrap capacitor. External circuitry should provide enough voltage headroom to facilitate charging.

When the HS-FET is on, BST exceeds is greater than V_{CC}, so the bootstrap capacitor cannot be charged.

In higher duty cycle operation conditions, the time period available for bootstrap charging is shorter, so the bootstrap capacitor may not charge sufficiently. If the external circuit does not have sufficient voltage and time to charge the bootstrap capacitor, additional external circuitry can be used to ensure the bootstrap voltage is within the normal operation range.

Low-Dropout Mode and BST Refresh

To improve dropout, the MPQ4313 is designed to operate at close to 100% duty cycle as long as the BST-to-SW pin voltage is above 2.5V. When the voltage from BST to SW drops below 2.5V, the HS-FET is turned off using a UVLO circuit, which allows the LS-FET to conduct and refresh the charge on the BST capacitor. In DCM mode or PSM mode, the LS-FET is forced on to refresh the BST voltage.

Since the supply current sourced from the BST capacitor is low, the HS-FET can remain on for more switching cycles than are required to refresh the capacitor. Thus, the effective duty cycle of the switching regulator is high.

The effective duty cycle during regulator dropout is mainly influenced by the voltage drops across the power MOSFET, the inductor resistance, the low-side diode, and the PCB resistance.

Enable Control

EN is a digital control pin that turns the regulator on and off. The MPQ4313 can be enabled in two ways:

First, it can be enabled by an external logic H/L signal. When EN is pulled below the falling threshold voltage (0.85V), the chip is put into the lowest shutdown current mode. Forcing this pin above the EN rising threshold voltage (1V) turns on the part.

The second method is via the programmable V_{IN} under-voltage lockout (UVLO) threshold. With a high enough V_{IN}, the chip can be enabled and disabled by the EN pin. The EN voltage (V_{EN}) can be set via resistor dividers (R_{EN1} + R_{EN2}) (see Figure 5).

Figure 5: Enable Divider Circuit

Programmable Frequency and Foldback

The MPQ4313 oscillating frequency can be programmed either by an external resistor (R_{FREQ}) from the FREQ pin to ground, or by a logic-level SYNC signal.

To get a specific switching frequency (f_{SW}), select the R_{FREQ} value following the f_{SW} vs. R_{FREQ} curve in the Typical Performance Characteristics (TPC) section on page 13. Note that f_{SW} folds back at high V_{IN} values to avoid triggering the minimum on time and V_{OUT} going out of regulation. The recommended f_{SW} for car battery applications is 350kHz to 1000kHz. Table 1 shows the recommended R_{FREQ} for common f_{SW} values. Applications that do not have a critical limit on f_{SW} or have a relatively low and stable V_{IN} can support higher frequencies.

Table 1: Recommended R_{FREQ} for Different f_{SW} Values

R _{FREQ} (kΩ)	f _{SW} (kHz)
86.6	350
80.6	380
75	410
62	470
59	500
54.9	530
49.9	590
45.3	640
41.2	700
37.4	760
34	830
30.9	910
28.7	960
26.1	1000

Frequency Spread Spectrum

The MPQ4313 uses a 12kHz modulation frequency with a 128-step triangular profile to spread the internal oscillator frequency over a 20% (±10%) window. The steps are fixed and independent of the setting oscillator frequency to optimize frequency spread spectrum (FSS) performance.

Figure 6: Spread Spectrum Scheme

Side bands are created by modulating the switching frequency with the triangle modulation waveform. The emission power of the fundamental switching frequency and its harmonics is distributed into smaller pieces. This significantly reduces the peak EMI noise.

Soft Start

Soft start (SS) is implemented to prevent the converter output voltage from overshooting during start-up.

When soft start begins, an internal current source begins charging the external soft-start capacitor. Once the soft-start voltage (V_{SS}) is below the internal reference (V_{REF}), V_{SS} overrides V_{REF} and the error amplifier uses V_{SS} as the reference. When V_{SS} exceeds V_{REF} , V_{REF} regains control.

The soft-start capacitance (C_{SS}) can be calculated with Equation (1):

$$C_{SS}(\text{nF}) = \frac{t_{SS}(\text{ms}) \times I_{SS}(\mu\text{A})}{V_{REF}(\text{V})} = 6.25 \times t_{SS}(\text{ms}) \quad (1)$$

The SS pins can be used for tracking and sequencing.

Pre-Biased Start-Up

For the MPQ4313, if $V_{FB} > V_{SS} - 150\text{mV}$ at start-up, which means output has a pre-biased voltage, neither the HS-FET nor LS-FET turns on until V_{SS} exceeds V_{FB} .

Thermal Shutdown

Thermal shutdown is implemented to prevent thermal runaway. When the silicon die temperature exceeds its upper threshold, it shuts down the power MOSFETs. When the temperature falls below its lower threshold, the chip is enabled again.

Current Comparator and Current Limit

The power MOSFET current is accurately sensed via a current-sense MOSFET. It is then fed to the high-speed current comparator for current mode

control. The current comparator takes this sensed current as one of its inputs. When the HS-FET is on, the comparator is blanked until the end of the turn-on transition to avoid noise. Then, the comparator compares the power switch current with the COMP voltage (V_{COMP}). When the sensed current exceeds V_{COMP} , the comparator outputs low to turn off the HS-FET. The maximum current of the internal power MOSFET is internally limited cycle by cycle.

Hiccup Protection

If the output is shorted to ground and the output voltage drops below 70% of its nominal output, the IC shuts down momentarily and begins discharging the soft-start capacitor. It restarts with a full soft start when the soft-start capacitor is fully discharged. This hiccup process repeats until the fault is removed.

Start-Up and Shutdown

If both V_{IN} and EN exceeds their respective thresholds, the chip starts. The reference block starts first, generating a stable reference voltage and current, and then the internal regulator is enabled. The regulator provides a stable supply for the remaining circuitries.

While the internal supply rail is up, an internal timer holds the MOSFET off for about $50\mu\text{s}$ to blank any start-up glitches. When the soft-start block is enabled, it keeps the SS output low to ensure the remaining circuitries are ready, then slowly ramps up.

Three events can shut down the chip: EN low, V_{IN} low, and thermal shutdown. In the event of a shutdown, the signaling path is blocked first to avoid any fault triggering. Then V_{COMP} and the internal supply rail are pulled down. The floating driver is not subject to this shutdown command, but its charging path is disabled.

Power Good Output

The MPQ4313 includes an open-drain power good (PG) output that indicates the output. A pull-up resistor to the power source is required if PG is used. The PG output goes high if the output voltage is within 95% to 105% of the nominal voltage, and it goes low if the output voltage is above 106.5% or below 93.5% of the nominal voltage.

SYNCIN and SYNCO

f_{sw} can be synced to the clock signal's rising edge applied at SYNCIN. The recommended SYNCIN frequency range is 350kHz to 1000kHz. Ensure that the SYNCIN off time is shorter than the internal oscillator period; otherwise, the internal clock turns on the HS-FET before reaching SYNCIN's rising edge. Besides the parasitic capacitance that is always present on the pad, there is no other limit on SYNCIN's pulse width. Thus, if the pulse width is too short, then a clear rising and falling edge may not exist due to the parasitic capacitance. A pulse longer than 100ns is recommended in application.

When applying SYNCIN in AAM, drive SYNCIN below its specified threshold (0.4V) or leave

SYNCIN floating before the MPQ4313 starts up and enters AAM. An external SYNCIN clock can also be added. To avoid floating SYNCIN while applying SYNCIN via an external clock, connect a resistor to GND. Given SYNCIN's drive capability, the resistor is recommended to be between 10k Ω and 51k Ω .

The SYNCO pin provides a default 180° phase-shifted clock to the internal oscillator. If there is no external SYNCIN clock, SYNCO provides a 180° phase-shifted clock that is compared with the internal clock. If there is an external SYNCIN clock, SYNCO provides a 180° phase-shifted clock that is compared with the external SYNCIN clock.

APPLICATION INFORMATION

Setting the Output Voltage

The external resistor divider connected to FB sets the output voltage (see Figure 8).

Figure 8: Feedback Network

Calculate R_{FB2} with Equation (2):

$$R_{FB2} = \frac{R_{FB1}}{\frac{V_{OUT}}{0.815V} - 1} \quad (2)$$

Table 2 lists the recommended feedback resistor values for common output voltages.

Table 2: Resistor Selection for Output Voltages

V _{OUT} (V)	R _{FB1} (kΩ)	R _{FB2} (kΩ)
3.3	100 (1%)	32.4 (1%)
5	100 (1%)	19.6 (1%)

Selecting the Input Capacitor

The step-down converter has a discontinuous input current, and requires a capacitor to supply AC current to the converter while maintaining the DC input voltage. For the best performance, use low-ESR capacitors. Ceramic capacitors with X5R or X7R dielectrics are highly recommended because of their low ESR and small temperature coefficients.

For most applications, use two 4.7μF to 10μF capacitors. It is strongly recommended to use another, lower-value capacitor (e.g. 0.1μF) with a small package size (0603) to absorb high-frequency switching noise. Place the smaller capacitor as close to V_{IN} and GND as possible.

Since C_{IN} absorbs the input switching current, it requires an adequate ripple current rating. The RMS current in the input capacitor can be estimated with Equation (3):

$$I_{CIN} = I_{LOAD} \times \sqrt{\frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right)} \quad (3)$$

The worst-case condition occurs at V_{IN} = 2V_{OUT}, calculated with Equation (4):

$$I_{CIN} = \frac{I_{LOAD}}{2} \quad (4)$$

For simplification, choose an input capacitor with an RMS current rating greater than half of the maximum load current.

The input capacitor can be electrolytic, tantalum, or ceramic. When using electrolytic or tantalum capacitors, add a small, high-quality ceramic capacitor (e.g. 0.1μF) as close to the IC as possible. When using ceramic capacitors, ensure that they have enough capacitance to provide a sufficient charge to prevent excessive voltage ripple at the input. The input voltage ripple caused by the capacitance can be estimated with Equation (5):

$$\Delta V_{IN} = \frac{I_{LOAD}}{f_{SW} \times C_{IN}} \times \frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (5)$$

Selecting the Output Capacitor

The output capacitor maintains the DC output voltage. Use ceramic, tantalum, or low-ESR electrolytic capacitors. For best results, use low-ESR capacitors to keep the output voltage ripple low. The output voltage ripple can be estimated with Equation (6):

$$\Delta V_{OUT} = \frac{V_{OUT}}{f_{SW} \times L} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \times \left(R_{ESR} + \frac{1}{8f_{SW} \times C_{OUT}}\right) \quad (6)$$

Where L is the inductor value, and R_{ESR} is the equivalent series resistance (ESR) value of the output capacitor.

For ceramic capacitors, the capacitance dominates the impedance at the switching frequency and causes the majority of the output voltage ripple.

For simplification, the output voltage ripple can be estimated with Equation (7):

$$\Delta V_{OUT} = \frac{V_{OUT}}{8 \times f_{SW}^2 \times L \times C_{OUT}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (7)$$

For tantalum or electrolytic capacitors, the ESR dominates the impedance at the switching frequency.

For simplification, the output ripple can be estimated with Equation (8):

$$\Delta V_{OUT} = \frac{V_{OUT}}{f_{SW} \times L} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \times R_{ESR} \quad (8)$$

The characteristics of the output capacitor also affect the stability of the regulation system. The MPQ4313 can be optimized for a wide range of capacitance and ESR values.

Selecting the Inductor

A 1μH to 10μH inductor with a DC current rating at least 25% greater than the maximum load current is recommended for most applications. For higher efficiency, choose an inductor with a lower DC resistance.

A larger-value inductor results in less ripple current and a lower output ripple voltage, but also has a larger physical size, higher series resistance, and lower saturation current. A good rule for determining the inductor value is to allow the inductor ripple current to be approximately 30% of the maximum load current. The inductance value can then be calculated with Equation (9):

$$L = \frac{V_{OUT}}{f_{SW} \times \Delta I_L} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (9)$$

Where ΔI_L is the peak-to-peak inductor ripple current.

Choose the inductor ripple current to be approximately 30% of the maximum load current. The maximum inductor peak current can be calculated with Equation (10):

$$I_{LP} = I_{LOAD} + \frac{V_{OUT}}{2f_{SW} \times L} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (10)$$

VIN UVLO Setting

The MPQ4313 has an internal, fixed under-voltage lockout (UVLO) threshold. The rising threshold is 3V, while the falling threshold is about 2.7V. For the applications that need a higher UVLO point, an external resistor divider between VIN and EN can be used to achieve a higher equivalent UVLO threshold (see Figure 9).

Figure 9: Adjustable UVLO Using EN Divider

The UVLO threshold can be calculated with Equation (11) and Equation (12):

$$INUV_{RISING} = \left(1 + \frac{R_{UP}}{R_{DOWN}}\right) \times V_{EN_RISING} \quad (11)$$

$$INUV_{FALLING} = \left(1 + \frac{R_{UP}}{R_{DOWN}}\right) \times V_{EN_FALLING} \quad (12)$$

Where V_{EN_RISING} is 1V, and $V_{EN_FALLING}$ is 0.85V.

External BST Diode and Resistor

An external BST diode can enhance the efficiency of the regulator when the duty cycle is high. A power supply between 2.5V and 5V can be used to power the external bootstrap diode. VCC or V_{OUT} is recommended to be this power supply in the circuit (see Figure 10).

Figure 10: Optional External Bootstrap Diode to Enhance Efficiency

The recommended external BST diode is IN4148, and the recommended BST capacitance is 0.1μF to 1μF. A resistor in series with the BST capacitor (R_{BST}) can reduce the SW rising rate and voltage spikes. This helps enhance EMI performance and reduce voltage stress at a high V_{IN} . A higher resistance is better for SW spike reduction but compromises efficiency. To make a tradeoff between EMI and efficiency, a $\leq 20\Omega$ R_{BST} is recommended.

Setting the VCC Capacitor

The VCC capacitor should be 10 times greater than the boost capacitor. A VCC capacitor with a nominal value above 68μF is not recommended.

PCB Layout Guidelines ⁽¹⁰⁾

Efficient PCB layout, especially for input capacitor placement, is critical for stable operation. A 4-layer layout is strongly recommended to achieve better thermal performance. For best results, refer to Figure 11 and follow the guidelines below:

1. Place symmetric input capacitors as close to VIN and GND as possible.
2. Use a large ground plane to connect directly to PGND.
3. Add vias near PGND if the bottom layer is a ground plane.
4. Ensure that the high-current paths at GND and VIN have short, direct, and wide traces.
5. Place the ceramic input capacitor, especially the small package size (0603) input bypass capacitor, as close to VIN and PGND as possible to minimize high-frequency noise.
6. Keep the connection between the input capacitor and VIN as short and wide as possible.
7. Place the VCC capacitor as close as possible to VCC and GND.
8. Route SW and BST away from sensitive analog areas, such as FB.
9. Place the feedback resistors close to the chip to ensure the trace that connects to FB is as short as possible.
10. Use multiple vias to connect the power planes to the internal layers.

Note:

10) The recommended PCB layout is based on Figure 12.

SECTION A-A

RECOMMENDED LAND PATTERN

NOTE:

- 1) THE LEAD SIDE IS WETTABLE.
- 2) ALL DIMENSIONS ARE IN MILLIMETERS.
- 3) LEAD COPLANARITY SHALL BE 0.08 MILLIMETERS MAX.
- 4) JEDEC REFERENCE IS MO-220.
- 5) DRAWING IS NOT TO SCALE.

CARRIER INFORMATION

Part Number	Package Description	Quantity /Reel	Quantity /Tube ⁽¹¹⁾	Quantity /Tray	Reel Diameter	Carrier Tape Width	Carrier Tape Pitch
MPQ4313GRE-AEC1-Z	QFN-20 (4mmx4mm)	5000	N/A	N/A	13in	12mm	8mm
MPQ4313GRE-33-AEC1-Z							
MPQ4313GRE-5-AEC1-Z							

Note:

11) N/A indicates “not available” in tubes. For 500-piece tape & reel prototype quantities, contact the factory. (Order code for 500-piece partial reel is “-P”, tape & reel dimensions remain the same as the full reel.)

REVISION HISTORY

Revision #	Revision Date	Description	Pages Updated
1.0	6/5/2020	Initial Release	-
1.1	11/8/2022	Updated the programmable frequency from “350kHz to 530kHz” to “350kHz to 1000kHz”	1, 4, 6, 20, 27, 29
		Deleted the Top Marking details for the fixed output versions (MPQ4313GRE-33-AEC1 and MPQ4313GRE-5-AEC1); updated the Package Reference image; updated “-Z” to “-Z”	3
		Updated the SYNCIN description	4
		Updated the BST absolute maximum rating from “V _{SW} + 5.5V” to “V _{SW} to 6V”; added the recommended V _{OUT} range; added Note 3; updated Note 4 and Note 5	5
		Deleted the original Note 7 for the HS current limit; updated the SYNCO phase shift condition	6
		Updated the Reverse Current Limit vs. Temperature and V _{IN} UVLO Threshold vs. Temperature curves to correspond to the electrical characteristics data	8
		Updated the f _{SW} vs. V _{IN} curve	13
		Added Note 8	14–15
		Modified the incorrect channel labels of the SYNCIN Operation and SYNCO Operation (middle left) waveforms	20
		Updated the Enable Control and Programmable Frequency and Foldback sections; added Table 1	27
		Updated the SYNCIN and SYNCO section	29
		Updated the Figure 12, Figure 13, and Figure 14 to include the typical I _{LIMIT}	33–34
Updated “-Z” to “-Z” and “-P” to “-P”	36
